The inner and outer back fats of 2 pigs which had been fed on a diet containing, finally, 50 per

Vol. 24, No. 4

cent. of a mixture of equal parts by weight of lard and cod liver oil were examined. The composition of the ration, the feeding and post-mortem findings on the animals have been reported elsewhere (Abst. 5334, Vol. 23). The back fats from one animal were separated by crystallisation from 10 per cent. solution in acetone at -40°C ., giving 68 per cent. of an insoluble glyceride fraction with an iodine value approximating to that of lard, and 32 per cent. of soluble glycerides with a much higher iodine value. From an estimation of the fatty acids in these 2 glycerides it was concluded that the lard and cod liver oil were absorbed almost unchanged and deposited additively along with typical "synthesised" pig fat in the depots. Depletion of anti-oxidant, vitamin E, then occasioned oxidation of the polyethenoid fatty acids of the cod liver oil.—W. Godden.

WENIGER, J. H. and FUNK, K. Untersuchungen über den Calcium- und Phosphorgehalt ganzer Schweinekörper. [Calcium and phosphorus content of entire bodies of pigs.] *Arch. Tierernährung*, 1953, **3**, 325-341. [Inst. Tierzucht, Martin Luther Univ., Halle, Wittenberg.]

After a brief outline of the occurrence and function of Ca and P in the animal body and the need for adequate supplies in the ration, earlier work, particularly that of Lawes and Gilbert, on the amount of Ca and P in pig carcasses is reviewed.

From material available from trials previously reported (Abst. 1327, Vol. 24) Ca and P were estimated in different parts of the carcasses from a large number of pigs of 5 breeds slaughtered at different liveweights. In all parts of the carcass, free of skin and bone, P greatly exceeds Ca. In the skeleton the reverse is true. With minor variation the ash of the total bones from pigs of 130 kg. liveweight contains 37.0 per cent. Ca and 17.89 per cent. P. Average values are given for the weight of fresh bones and ash as a percentage of the fresh bone for 209 pigs of 5 breeds and at 5 different liveweights. The percentage of ash rises steadily from 17.3 at 30 kg. liveweight to 24.2 at 150 kg. liveweight. A table is given showing the calculated weight of Ca and P in the bones per kg. liveweight from 1 to 150 kg. liveweight. Figures for 3 breeds of pigs at 130 kg. liveweight show that pigs with a high fat content, owing to lower proportion of bone in the carcass, have lower total Ca and P contents and a narrower Ca : P ratio. Three newborn piglets were analysed and found to contain on the average 10.81 g. Ca and 6.32 g. P per kg. liveweight, figures in close agreement with those of Bartels (*Arch. Tierernährung u. Tierzucht*, 1930, **3**, 287) and Radeff (*ibid.*, 1930, **3**, 639).

STOB, M., ANDREWS, F. N. and ZARROW, M. X. **The detection of residual hormone in the meat of animals treated with synthetic estrogens.** *Amer. J. Vet. Res.*, 1954, **15**, 319-322. [Dept. Animal Husb., Purdue Univ., Lafayette, Ind.]

A preliminary experiment with mice from which the ovaries had been removed and which were fed on a standard diet with or without the addition of diethylstilboestrol showed that, without the hormone, atrophy of the uterus was almost complete 2 weeks after removal of the ovaries. Assay by uterine weight for diethylstilboestrol given by mouth was 4 times as sensitive as the vaginal smear technique and gave significant results with 0.0055 μ g. hormone per g. ration. This method was used for the examination of beef muscle taken from the neck of control steers and of others which had had an implant of diethylstilboestrol or a subcutaneous injection of an emulsified hormone preparation containing both dieneoestrol and progesterone, 168 days before slaughter. The results indicated that beef from animals treated in this way did not contain more than 0.01 μ g. residual hormone per g. dried meat. A more detailed report of work with other species and other tissues is to be presented elsewhere.—W. Godden.

STANSBY, M. E. **Composition of certain species of fresh-water fish. 1. Introduction: the determination of the variation of composition of fish.** *Food Res.*, 1954, **19**, 231-234. [Pacific Coast and Alaska Technol. Res., Fish and Wildlife Serv., Seattle, Wash.]

Because of the variability in composition of fish, and inadequate sampling, many of the figures quoted are worthless. The Fish and Wildlife Service plans to collect more satisfactory data for freshwater fish. The method of preparing samples for analysis is briefly described. Results, based on 16 specimens of each species, will be reported for 5 species of Lake Erie fish in part 2 of this series.

DESHPANDE, P. D. and RADHAKRISHNA RAO, M. V. **Nitrogen complex and amino-acid composition**

of (i) amaranth (*Amaranthus gangeticus*) and (ii) aconite bean (*Phaseolus aconitifolius*). *Indian J. Med. Res.*, 1954, **42**, 77-83. [Dept. Nutrit., Haffkine Inst., Bombay 12.]

Air-dried amaranth (*Amaranthus gangeticus*) leaves had the following percentage composition: moisture 8.77, N 4.76, ether extract 4.70, ash 17.13, carbohydrate (by difference) 39.17, Ca 3.16, P 0.64, MgO 2.50, and contained 0.12 mg. Fe per 100 g. Much of the N was not extractable by water, 5 per cent. NaCl, 70 per cent. alcohol or 0.1 per cent. NaOH and of that extracted nearly two-thirds was N.P.N. The leaves contained between 1 and 2 per cent., on a dry basis, of lysine, leucine, isoleucine, arginine and valine, estimated microbiologically, but were low in cystine and methionine.

Powdered aconite beans (*Phaseolus aconitifolius*) had the following percentage composition: moisture 9.48, N 3.91, ether extract 1.21, ash 3.10, carbohydrate (by difference) 61.76, Ca 0.22, P 0.10, MgO 0.84, and contained 0.009 mg. Fe per 100 g. Nearly 90 per cent. of the N was extractable by alkali and at least four-fifths of this was protein. The beans contained between 1 and 2 per cent. of lysine, leucine, isoleucine, phenylalanine and tyrosine, but were low in cystine and methionine.

Both are considered likely to be valuable as supplements to rice or wheat diets, on account of their lysine.—W. M. Deans.

4277

THOMAS, H. R. and LEWIS, M. N. **Sodium values of seven frozen vegetables.** *J. Amer. Dietetic Assoc.*, 1954, **30**, 327-328. [Dept. Dietetics, Ohio State Univ. Hosp., Columbus.]

There were variations in the sodium content of different samples of a vegetable. Average values in mg. per 100 g. material as purchased were: asparagus 1.89, broccoli buds 19.94, cauliflower 16.22, green beans 1.26, Lima beans 151.49, peas 129.95, spinach 42.41.

In low-sodium diets fresh Lima beans and peas are preferable to the frozen products.

PARKS, V. B., HEWSTON, E. M., MARSHALL, M. W. and BRUINOOG, A. M. **Developing breads of higher nutritive value.** *J. Amer. Dietetic Assoc.*, 1954, **30**, 245-250. [Bur. Human Nutrit., U.S. Dept. Agric., Washington, D.C.]

The objective was the production of breads rich in protein, calcium and vitamin B₁ to improve the nutritive value of school lunches. Six breads were prepared with 5.5 to 10 per cent. non-fat milk

N.A. and R., October 1954

solids: they were white, raisin, wholewheat-white, soya-white, soya-wheatgerm-white and brewer's-yeast-white. Enriched white flour was used. Commercial baking tests, palatability tests and analyses were made. All except the bread containing extra yeast could be baked commercially. The yeast bread was the least palatable. Estimation of nutritive value of the breads from tables of composition of ingredients underestimated Ca content by about 5 per cent. and overestimated vitamin B₁ content by 25 per cent., except for the yeast bread where vitamin B₁ was underestimated by 33 per cent. as compared with the results of chemical analyses. Analytical data showed that the high levels of milk solids in the breads increased Ca and protein content at the expense of vitamin B₁ content, since the amount of flour was reduced.

MARKUZE, Z. and SZACHOWSKA, M. Zawartość wapnia, fosforu i żelaza w mąkach pszennych i żytnich różnego przezięcia. [The calcium, phosphorus and iron contents of wheat and rye flour of different extraction rates.] *Rocz. Państwowego Zakł. Hig.*, 1954, 5, 79-84. [Z Zakładu Badania Żywności i Przedmiotów Użytku PZH.] Russian and English summaries.]

Three samples of wheat flour and 3 of rye flour of different extraction rates were analysed. In the wheat flours 100 g. dry matter contained 0.56 to 1.40 g. ash, 1.5 to 3.5 mg. Fe, 24 to 41 mg. Ca and 150 to 332 mg. total P. For the rye flours the values were 0.78 to 1.83, 1.6 to 4.0, 23 to 44 and 143 to 406, respectively. All the values increased as the rate of extraction rose. [From summary.]

HILL, R. and TYLER, C. The effect of increasing acidity on the solubility of calcium, magnesium and phosphorus in certain cereals and pure salts. *J. Agric. Sci.*, 1954, 44, 293-305. [Royal Agric. Coll., Cirencester.]

The solubilities of Ca, Mg, total P, phytate and non-phytate P in bran, wheatmeal and oatmeal alone or with the addition of varying amounts of CaCO₃ were measured over the pH range 6.5 to 1.0. Similar measurements were made for certain mixtures of CaCO₃, Na₃PO₄, phytin, sodium phytate, precipitated calcium phosphate and trimagnesium phosphate. In each case 10 g. of the cereal was mixed with 10 times its weight of water of which the pH had been adjusted by addition of N HCl. The reaction proceeded for 1 hr., after which the supernatant liquid was poured off, centrifuged and filtered, and estimations of pH and soluble constituents were made on the filtrate.

Vol. 24, No. 4

The Ca in bran and wheat was not so soluble as that in oats but in all cases solubility increased, most rapidly in oats, as the pH decreased. Mg dissolved more readily from the cereals at higher pH values than did Ca. The solubility of Ca in CaCO₃ added to the cereals varied with the cereal, but it was always completely soluble at pH 3.0 and below. The curves for solubility of total P in cereals with reference to pH varied with the cereal. They all showed a rise at first as pH decreased from 6.0 to a maximum at about 4.5 to 5.0 and then a more or less marked and rapid fall to a minimum at pH 2.0, followed by a further steep rise in wheat and oats, slight in bran, to pH 0.5. The effect of added CaCO₃ on the shape of the solubility curve varied with the cereal and with the amount of CaCO₃ added. The results for solubility of phytate P were affected by the activity of phytase present in the cereal, which varied with the pH. This effect was negligible in oats, as the enzyme was absent or inactive.—W. Godden.

4281

HILL, R. and TYLER, C. The influence of time, temperature, pH and calcium carbonate on the activity of the phytase of certain cereals. *J. Agric. Sci.*, 1954, 44, 306-310. [Royal Agric. Coll., Cirencester.]

The hydrolysis of phytate in wheat, bran and oats by the phytase present was studied under different conditions. Oats were shown to have almost no phytase activity. The optimum pH for wheat phytase was 5.0 to 5.1, but activity persisted down to pH 3.0. If the acidity was reduced to pH 2.5 for 5 min. and then restored to pH 5.0 by the addition of NaHCO₃, the phytase did not recover its activity. With rise in temperature from 15° to 50° C. there was a uniform increase in the rate of hydrolysis which decreased as the reaction proceeded but continued until only a very small amount of soluble substrate remained. Ca present under conditions in which it could form insoluble phytate reduced phytate hydrolysis to a considerable degree.—W. Godden.

4282

HILL, R. and TYLER, C. The effect of decreasing acidity on the solubility of calcium, magnesium and phosphorus in bran and certain pure salt solutions. *J. Agric. Sci.*, 1954, 44, 311-323. [Royal Agric. Coll., Cirencester.]

Two lots of bran were prepared from the same bulk sample; one was acidified to pH 2.0 with HCl and the other to pH 5.1. The volumes of liquid were the same in each case. Both samples were kept for 2 hr. at 37° C. after which the pH of the second sample was reduced to 2.0 by adding acid. At pH 2.0 all phytase was destroyed (see preceding abstract). Sample 2 is referred to as

"hydrolysed" and sample 1 as "unhydrolysed" bran. The precipitation of Ca, Mg and P from these samples as the pH was raised stepwise to 6.5 by the addition of 1.0 N NaCO₃ was studied using added amounts of 50, 200 or 800 mg. Ca as CaCO₃.

In both samples precipitation of Ca was only slightly increased by raising pH but was greater in amount and began at lower pH in the unhydrolysed than in the hydrolysed bran. When 50 mg. Ca as CaCO₃ was added it was almost completely precipitated at pH 6.5, somewhat less being precipitated over the whole pH range from the hydrolysed than the unhydrolysed bran. With the higher amounts of added Ca the changes were of a similar type, except that at the higher pH precipitation was not so complete. At pH 2.0 over 90 per cent. of the total Mg in both samples of bran was soluble. With hydrolysed bran in none of the mixtures was 50 per cent. or more of the Mg precipitated, even at pH 6.5 with added Ca. In the mixtures containing unhydrolysed bran, when no Ca was added 72.5 per cent. of the Mg was precipitated at pH 6.5 and with 50 mg. Ca added 56.0 per cent.

With unhydrolysed bran the curves for soluble phytate P and soluble total P were almost parallel and therefore only phytate P solubilities need be considered. The soluble phytate P value in the bran alone rose very slowly as pH increased from 2.0 to a maximum at about 5.0 and then decreased by about 50 per cent. at pH 6.4. As the amount of Ca added rose from 50 to 800 mg. the solubility of phytate P began to decrease at lower pH until with 800 g. Ca the decrease began at pH 3.0 and precipitation was almost complete at 4.5. With 50 mg. Ca present the amounts of Ca and Mg precipitated at pH 6.5 were insufficient to produce a base-saturated phytate but with 200 mg. present penta- and hexacalcium phytates were precipitated at pH 3.5 to 5.0. At low pH, with 800 mg. Ca present, the penta-salt, but at high pH the hexa-salt, appeared to be precipitated.

With hydrolysed bran alone, increasing the pH caused practically no precipitation of P despite the presence of 41.8 mg. phytate P. With 50 mg. Ca added 50 per cent. of the total P was precipitated at pH 6.5 and with 200 and 800 mg. Ca present this level of precipitation was attained at pH 5.5 and 4.6, respectively. In all cases phytate P was precipitated somewhat earlier than phosphate P. With 50 mg. Ca present the compound precipitated at pH 4.0 to 5.8 was pentacalcium phytate. At pH 6.0 the ratio of Ca to Mg corresponded to base-saturated phosphate or phytate as tetracalcium dimagnesium phytate. With higher amounts of Ca added the precipitate consisted mainly of hexacalcium phytate and tri-calcium phosphate.

Similar experiments with phytin, sodium phytate and sodium phosphate, with varying amounts

of added CaCO₃, are reported and the results indicate that not only the ratio of Ca : P but the actual concentrations present affect the degree of precipitation.

These results are considered in relation to the precipitations which are likely to occur in the small intestine, and the possible effects of such precipitations on absorption of Ca and P are discussed.—W. Godden.

4283

HILL, R. and TYLER, C. **The reaction between phytate and protein.** *J. Agric. Sci.*, 1954, **44**, 324-326. [Royal Agric. Coll., Cirencester.]

In the first paper of this series (see above Absts.) it was found that the phytate P in bran, wheat and oats was less soluble at pH about 2.2 than at higher and lower pH values. Earlier work by Fontaine *et al.* (Abst. 2760, Vol. 16) suggested that protein might be responsible for such results. A study of the solubility of phytate P in the presence of wheat gluten over the pH range 0.5 to 6.5 showed that the fall in solubility in the region of pH 2.5 was due to reaction with protein and that this reaction could be reduced considerably by adding Ca.—W. Godden.

DAVIES, C. W. and HUGHES, R. B. The organic acids of grass extracts. *J. Sci. Food Agric.*, 1954, **5**, 200-205. [Edward Davies Chem. Labs., Univ. Coll. Wales, Aberystwyth.]

Aqueous extracts were made of heat-dried samples of perennial rye, cocksfoot and timothy grasses. After concentration and the removal of amino-acids by Zeo-Karb 215 they were examined by ion exchange chromatography. Although the proportions of the acids in them varied the grasses were closely similar and 12 organic acids were found to be present of which 6, acetic, lactic, succinic, malic, malonic, and citric, were identified. The lactic acid may have originated by catalytic action in the resin column. Oxalic, tartaric and isocitric acids were not detected.

Preliminary studies of changes during growth and of diurnal variations are recorded. These and the study of losses of volatile acids during drying and extraction are being pursued.

4295

HULME, A. C. and RICHARDSON, A. The non-volatile organic acids of grass. *J. Sci. Food Agric.*, 1954, **5**, 221-225. [Ditton Lab., D.S.I.R., East Malling, Kent.]

The non-volatile organic acids were extracted from a dried mixture of meadow foxtail and meadow fescue by 80 to 85 per cent. alcohol. After the alcohol was evaporated the residual liquid was decolorised with de-activated charcoal, diluted to 500 ml. with water and passed down a column of Zeo-Karb 215 to remove all amino-acids and cations. The effluent and washings were passed down a column of Amberlite IR₄B on which the acids were absorbed. The column was

washed with water to remove all sugars and the acids were then displaced by 0.1 N HCl. The eluate and washings, after removal of CO₂, were passed down a Dowex 2 column from which, after washing, the acids were again displaced by 0.1 N HCl and successive 2 ml. fractions were collected. These fractions were submitted to paper chromatography. Quinic acid was proved to be present and the presence of succinic, malic, malonic and citric acids was indicated (*cf.* preceding Abst.). Two other acids, not identified, one of which appeared to be allied constitutionally to quinic acid, were present. In an aqueous extract of the dried grasses chlorogenic acid was found.

4299

DOUGALL, H. W. **Fertilizer experiments on grassland in the Kenya Highlands.** *E. African Agric. J.*, 1954, 19, 171-178. [Dept. Agric., Kenya.]

A series of plots were laid down to test the effect of factorial combination of P as superphosphate and N as sulphate of ammonia on the establishment of leys and on the productivity of established grass and natural pastures, including rough grazing. Herbage was cut when it had reached a stage of growth considered suitable for grazing and on the permanent grass a further application of N was

given after each cutting. Yields of fresh material were recorded and samples of the first cut only were taken for estimation of H₂O, P and Ca.

For ley establishment a single dressing of 1½ cwt. sulphate of ammonia (20 per cent. N) per acre to the seed bed was beneficial but higher dressings did not seem justifiable. The dressing of superphosphate (18 per cent. citric-soluble P₂O₅) should rarely exceed 3 cwt. per acre. On permanent grass dressings of N may be beneficial at intervals during the growing season but only if the pasture is fenced and adequately stocked and has adequate water supplies. The dressing of superphosphate should rarely exceed 3 cwt. per acre.

In ley establishment phosphate fertilisers increased the P percentage in the dry matter, but reduced that of Ca. The yields per acre of crude protein, P and Ca in the crop were all increased. On permanent pasture both percentage in dry matter and yield of crude protein, P and Ca per acre were all increased.

In newly sown leys N, apart from very high dressings, had little effect on the yield of crude protein, P or Ca per acre, but in permanent pasture the yields of all three increased as the dressing increased. The effects of pH of the soil and rainfall during the month before cuttings on the above results are briefly discussed.

N.A. and R., October 1954

Five types of pasture are described and the areas which they cover are outlined on a coloured map. The main plant species occurring in them are: type 1, Danga (*Heteropogon contortus*, P.B.) and Vero (*Hyparrhenia rufa*, Stapf.); type 2, Ahipisika, which includes *Stenotaphrum dimidiatum*, R.Br., *Axonopus compressus*, P.B. and *Paspalum conjugatum*, Berg, and Tenina (*Imperata cylindrica*, L.); type 3, Kifafa (*Aristida* spp.) and *Trichopteryx stipoides*, Hackel; type 4 is a mixture of types 1 and 3; type 5 is a mixture of 2 with Kifafa and Vero. Local and botanical names of other species which also exist on these different types are listed. A table is given showing the relative numbers of bulls, bullocks, male calves, cows and heifers which graze on these areas and also the total cattle population for 16 districts in the region under survey. An appendix contains climatological data for the different types of pasture and also data on the composition of 5 main species of plants.

MOON, F. E. **The composition and nutritive value of hay grown in the east of Scotland and the influence of late applications of nitrogenous fertilisers.** *J. Agric. Sci.*, 1954, **44**, 140-151. [Edinburgh and E. Scotland Coll. Agric.]

Results of experiments made between 1948 and 1951 inclusive are reported.

The composition of unfertilised hays from all centres in all years is given in detail. Average values were as follows in the order total nutrients in per cent. dry matter, digestibility per cent. (sheep), digestible nutrients in per cent. dry matter: crude protein 6.32, 40.0, 2.92, ether extract 1.44, 40.3, 0.61, crude fibre 33.95, 56.7, 19.65, N-free extract 51.97, 59.2, 30.27. Average starch equivalent was 33.8.

Application of sodium nitrate or "Nitrochalk" 10 to 20 days before cutting produced a significant increase in the protein content of grasses, mostly in the digestible protein fraction. The protein of clover was unaffected. Treatment with 1 to 3 cwt. fertiliser per acre produced an average increase of 46 per cent. in the digestible protein of seeds hays and of 31 per cent. in meadow hays.

Significant increases in the yield of aftermath from late fertiliser treatments often amounted to 4 to 5 cwt. dry matter per acre. The botanical composition of aftermath on meadow was not usually affected but in seeds aftermath, clovers were greatly suppressed.

N recovery amounted to 30 to 35 per cent. in the hay crop and up to 25 per cent. in aftermath.

It was concluded that it would be profitable to use N fertiliser, applied shortly before cutting, on hay crops, particularly seeds hays, grown in the east of Scotland.—P. C. Jowsey.

BROWN, W. O. **Composition and quality of crop silages made in Northern Ireland.** *Res. Exp. Rec. Minist. Agric. N. Ireland*, 1952, 25-27. [Minist. Agric. N. Ireland.]

The records of analyses of 321 samples of cereal-legume silage submitted to the Ministry during 1940 to 1952 have been surveyed and the classified results are compared with those for grass silage samples during 1940 to 1948 (see Abst. 4842, Vol. 20). Before 1946 most of the samples came from towers or upright containers, after 1946 mainly from trenches. About half the samples had less than 20 per cent. dry matter and in this sense were unsatisfactory, this being particularly true since 1946. Only about 20 per cent. of the samples could be regarded as balanced for milk production on the basis of protein content; 46 per cent. contained less than 12 per cent. protein. The pH value of 30 per cent. was below 4.2; 45 per cent. had values above 4.6. Appraisal by colour and smell classified 20 per cent. of the silages before 1946 as overheated; after that year only 8 per cent. were overheated but the percentage classed as sour or butyric rose from 16 to 36 per cent.

JÓHANNESSON, B. and KRISTJÁNSDÓTTIR, K. **Efnasamsetning grass á ýmsum aldursstigum og hæfni þess til votheysgerðar. [Chemical composition of grass at different stages of growth and its suitability for making silage.]** *Atvinnudeild Háskólans Reykjavík Rit Landbúnaðardeilda B-Flokkur*, No. 6, 1954, 21-37. English summary.

Grass was sampled at different stages of growth. As the season advanced protein decreased and fibre, soluble sugars and carbohydrates increased. Varietal differences, seasonal variations and soil fertility level affected the slope of the time-composition curves.

Chopped grass at different stages of growth was ensiled in glass jars, sealed to exclude air and sampled at intervals of from 20 to 120 days after storage.

Grass cut at the earliest stages of growth generally reached the lowest pH in spite of the low content of sugars and hydrolysable carbohydrate. It was computed that at least 80 per cent. more carbohydrates were converted to lactic acid in a sample cut at the beginning of June than in one cut a month later.

During storage in the laboratory silos a great breakdown of protein occurred. For example, grass cut early in June contained 23.0 per cent. protein and after storage for 4 months the silage contained 8.5 per cent. A sample cut early in July contained 10.5 per cent. protein and after storage for 3 months contained 4.9 per cent. (From summary.)—P. C. Jowsey.

HOLLENBECK, C. M., DANNER, W. E. and MAHONEY, J. F. **The stability of procaine penicillin in feeds.** *Poultry Sci.*, 1954, **33**, 425-427. [Res. Labs., Chem. Div., Merck and Co., Inc.]

Procaine penicillin, obtained from a number of different sources, was incorporated at a level of 20 g. per ton into commercial poultry rations, which were then pelleted and stored with a 10 per cent. moisture content.

After 30 days of storage at 100° F., assay of pellets for penicillin activity by the method of Esposito and Williams (*Federation Proc.*, 1952, **11**, 208) gave values ranging from 10 to 88 per cent. of the original activity for pellets made up with procaine penicillin preparations of the type used in pharmacy. Ten feed mixes prepared by a different method [details not stated] gave a mean recovery of 97 per cent. after this period of storage.

Storage for the same period at 75° F. caused less destruction even with "pharmaceutical" types of procaine penicillin preparations, the recoveries ranging from 14 to 100 per cent. of the original activity.—K. J. Carpenter.

CLAYTON, M. M., BABCOCK, M. J., FOSTER, W. D., STREGEVSKY, S., TUCKER, R. E., WERTZ, A. W. and WILLIAMS, H. H. **A referee blood experiment involving the use of microchemical methods.** *J. Nutrition*, 1954, **52**, 383-393. [Dept. Home Econ., Maine Agric. Exp. Stat., Orono.]

Samples of serum frozen and packed in dry ice were sent to 6 laboratories for microchemical estimation by the method of Bessey *et al.* (György, "Vitamin Methods I", 1950, Acad. Press, Inc., New York) of Hb, ascorbic acid, vitamin A and carotene.

Replicate estimations were consistent at each individual laboratory but there were large differences between laboratories, some having consistently high and some low results for each estimation. For ascorbic acid and carotene the variations were of a magnitude similar to the variations found in any individual subject from day to day. Duplicate readings at the 6 laboratories on the Beckman spectrophotometer varied less than the chemical estimations of which they were part.

A list is given of the causes of differences and of precautions to be taken in order to minimise them.

SQUIBB, R. L., GUZMAN, M. A. and SCRIMSHAW, N. S. **Effect of high environmental temperatures on metabolism. 1. Growth and blood constituents of rats exposed to 94° F. for 72 hours.** *J. Nutrition*, 1954, **52**, 155-163. [Inst. Agropecuario Nac., Guatemala City.]

Male adult rats received a synthetic diet to appetite or with intake restricted to 5 g. daily. For 72 hr. they were kept at a temperature of 76° F. and humidity from 35 to 75 per cent., or of 94° F. and humidity from 50 to 75 per cent. Several tests were made. At the end of the test the rats were killed and total protein, riboflavin, total carotenoids, vitamin A, ascorbic acid, alkaline phosphatase and phosphorus were estimated in the blood serum.

With food to appetite the rats at the higher temperature reduced their food intake significantly, lost much weight and had the higher mortality rate. The level of total carotenoids was not affected but riboflavin, vitamin A, ascorbic acid and alkaline phosphatase were significantly lowered, and total serum protein rose significantly. When the food intake was restricted to 5 g. daily, the rats at both temperatures lost weight to the same extent. At the high temperature, serum values for carotenoids, riboflavin, alkaline phosphatase and P were unaffected, but those for vitamin A and ascorbic acid were significantly lowered; serum protein was raised in 3 out of 4 tests, but the average increase was not significant.

BREÅKKAN, O. R. and PROBST, A. Vitaminer i norsk fisk. 1. Nikotinsyre-, riboflavin-, panto- tensyre-, vitamin B₁₂- og vitamin A-innholdet i hel fisk og forskjellige organer fra fersk sild (*Clupea harengus*) og makrell (*Scomber scombrus*). [Vitamins in Norwegian fish. 1. The content of nicotinic acid, riboflavin, pantothenic acid, vitamin B₁₂ and vitamin A in the whole fish and different organs of herring (*Clupea harengus*) and mackerel (*Scomber scombrus*).] *Fiskeridirektoratets Skr., Ser. Teknol. Under- søkelser*, 1953, **11**, No. 13, pp. 10. English summary.

Fish were sampled, fresh from the boats, at the time when they were biggest and the catches heaviest. Methods of preparation are described; the B vitamins were estimated by microbiological methods, vitamin A spectrophotometrically (conversion factor 1900), except where the amount to be estimated was small, when the SbCl₃ reaction was used. It was found impossible to remove riboflavin from hard roe by acid extraction; digestion with papain and takadiastase was satisfactory but only a few samples were thus treated.

Values for number, weight, dry matter, fat, ash, protein (N × 6.25), and the vitamins are presented for herring and mackerel separately, distinguishing whole fish, muscle, liver, hard and soft

roe, and the remainder of the viscera [in the tables called intestines], for male and female separately.

The B vitamin values in µg. per g. without distinction of sex, for herring and then mackerel, whole fish, muscle, liver, hard and soft roe were as follows: nicotinic acid 30.5, 39, 50, 18.8, 14.3; 63, 93.5, 79, 21, 22; riboflavin 2.6, 3.3, 7.4 (1.7), 2.6; 5.7, 3.6, 11.3 (2.2), 9.2; pantothenic acid 9.3, 9.5, 21.0, 14, 14.3; 10.7, 10.3, 33.3, 11.8, 46; vitamin B₁₂ 0.11, 0.14, 0.39, 0.07, 0.11; 0.14, 0.12, 0.52, 0.07, 0.30. Vitamin A values in I.U. per g. in the same sequence were: 13, trace, 610, —, 1.5; 96, trace, 4670, —, 5.—I. Leitch.

LECOQ, R. Essai de quelques facteurs vitamini- ques, introduits par voie intraveineuse, sur la réserve alcaline du plasma sanguin. [Trial of some vitamin factors introduced intravenously on the alkali reserve of the blood plasma.] *C.R. Soc. Biol.*, 1954, **148**, 71-74.

Adult rabbits received intravenous injections of hesperidoside, leucocyanidol, both members of the vitamin P group, or biotin or cyanocobalamin (vitamin B₁₂) dissolved in physiological saline. The alkali reserve of the blood plasma after 6, 8 and 24 hr. was estimated by Van Slyke's method.

Hesperidoside and biotin caused a rise in alkali reserve while leucocyanidol and vitamin B₁₂ caused a marked and prolonged fall. The effect of the latter substances was thought possibly to be an attempt of the body to counteract the acidosis of vitamin P deficiency and pernicious anaemia by the transference of base from the plasma to the tissues with a consequent fall in alkali reserve.

KAMATH, G. G. and MAGAR, N. G. **Ultra-violet absorption characteristics of some Indian shark-liver oils.** *Indian J. Med. Res.*, 1953, **41**, 339-347. [Dept. Biochem., Inst. Sci., Bombay, 1.]

Vitamin A was estimated in the liver oil of sharks caught off the Bombay coast. The values in I.U. per g. found by measuring the gross absorption at 328 mµ. and multiplying by 1600 were for boladi (*Rhinoptera javanica*) 1000, khada mushi (*Carcharinus melanopterus*) 10,600, pakat (ray, *Dasybatus uarnak*) 2300, pitori (*Carcharinus limbatus*) 15,400 to 37,300, ranja (skate, *Rhynchobatus*

djeddensis) 2200 and waghbeer (*Galeocerdo tigrinus*) 1800. Values of the same order were obtained by applying the correction procedure of Morton and Stubbs and multiplying by 1800, or by estimations with glycerol dichlorohydrin. Presence of anti-oxidants such as propyl gallate, *nordihydroguaia-*retic acid and various commercial preparations did not significantly affect the absorption at 328 m μ . in the concentrations used.—T. Moore.

NÚÑEZ, G. Chromatographie de partage des substances liposolubles. 2. Chromatographie sur papier des caroténoïdes. [Partition chromatography of fat-soluble substances. 2. Paper chromatography of carotenoids.] *Bull. Soc. Chim. biol.*, 1954, **36**, 411–413.

The R_F values were measured of certain carotenoids on paper previously treated with olive oil. Increasing the concentration of oil on the paper decreased the R_F . Different alcohols saturated with olive oil were used as developers, that most used being ethanol with varying proportions of pyridine. The R_F values were raised by increasing the proportion of pyridine. Carotene, lycopene and some xanthophylls could be separated, but α - and β -carotene, and zeaxanthin and xanthophyll, could not.—V. H. Booth.

4320

LECOMTE, R. and SEILLEUR, P. Extraction des carotènes en vue de leur détermination. [Extraction of carotenes with a view to their estimation.] *Bull. Inst. agronom. Gembloux*, 1953, **21**, No. 3/4, 14–25.

A method is described for extracting carotene from vegetable tissues. Fresh vegetable material was chopped in a straw cutter and mixed. Between 1 and 2 kg. was frozen at -70°C . under CO_2 and ground in a hammer mill. The powder, still under CO_2 , was transferred to a lyophiliser. After lyophilisation, samples of from 0.5 to 4 g. were weighed into an Erlenmeyer flask and covered with Allihn's refrigerant. One hundred ml. of light petroleum were added, and the mixture was boiled for 15 min. under reflux. The flask was cooled and a portion of the solution was pipetted out for chromatography. In comparison with certain older methods, the method yielded higher carotene values with a lower coefficient of variation

which differed with the nature of the vegetable extracted but was always less than 3.2 per cent.

Dry material was ground in a hammer mill and the extraction with light petroleum followed a similar course.—V. H. Booth.

4321

GARBERS, C. F., EUGSTER, C. H. and KARRER, P. Über die Vitamin-A-Wirkung des *cis*- β -Carotins C (mit behinderter Doppelbindung). [Vitamin A activity of *cis*- β -carotene C (with hindered double bond).] *Helv. chim. Acta*, 1954, **37**, 382. [Chem. Inst., Univ. Zürich.]

Estimated by the rat growth method, *cis*- β -carotene C had about 20 to 25 per cent. of the vitamin A activity of all-*trans*- β -carotene. The C isomer is less stable than other *cis*-isomers of β -carotene, which may explain its inferior activity.

BICKOFF, E. M., LIVINGSTON, A. L., BAILEY, G. F. and THOMPSON, C. R. Xanthophylls in fresh and dehydrated alfalfa. *J. Agric. Food Chem.*, 1954, **2**, 563–567. [W. Utilisation Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany 6, Calif.]

A Chilean variety of alfalfa, grown near the laboratory, was harvested at the pre-bloom stage and the pigments were extracted with acetone. The washed extract was chromatographed on a column of calcium hydroxide with or without diatomaceous earth. An extract of a sample of commercial dehydrated alfalfa meal was prepared and chromatographed on a magnesium oxide and Celite column. Of the xanthophylls present in the fresh material, lutein constituted 40 per cent., violaxanthin 34, cryptoxanthin 4, zeaxanthin 2 and neoxanthin 19, making a total of 99 per cent. Seven minor bands also were detected. The same 5 pigments accounted for 87 per cent. of the xanthophylls present in the dehydrated alfalfa meal; of the total carotenoids present in it, 22.6 per cent. was β -carotene.—I. M. Sharman.

KRAUSE, R. F., COOVER, M. O. and POWELL, L. T. Conversion of C¹⁴ carotene to a non-saponifiable substance or substances in the rat. *Proc. Soc. Exp. Biol. Med.*, 1954, 85, 317-319. [Dept. Biochem., Sch. Med., W. Virginia Univ., Morgantown.]

Carotene uniformly labelled with ¹⁴C was suspended in water with Tween 80 as emulsifier, and given by stomach tube to two male rats. The rats were killed 6 and 24 hr. later, and the non-saponifiable substance was extracted from the liver, small intestine and extrahepato-intestinal tissue. The extracts were freed from carotene by chromatography. The non-saponifiable substances were extracted also from the faeces. The vitamin A content of the tissues was estimated by the SbCl₃ method, and the carotene content of the faeces by measuring the extinction of the extract at 450 mμ. The radio-activity of the dry extracts was measured under an end-window Geiger Müller tube.

Vol. 24, No. 4

The animal killed after 24 hr. absorbed 30.5 per cent. of the total ¹⁴C given and the animal killed after 6 hr., 53.8 per cent. In both animals the rest of the carotene was accounted for in the faeces. The liver, small intestine and other tissues contained, respectively, 4.4, 6.1 and 20.0 per cent. of the ¹⁴C given in the animal killed after 24 hr., and 6.7, 14.1 and 33.0 per cent. in the animal killed after 6 hr. The content of vitamin A in the three tissues was much the same for both rats and was approximately 1000, 30 and 90 μg., respectively, for the two rats.—R. J. Ward.

4329

HIGH, E. G. Studies on the absorption, deposition and depletion of vitamin A in the rat. *Arch. Biochem. Biophys.*, 1954, 49, 19-29. [Lab. Biochem. Res., Prairie View Agric. and Mech. Coll., Tex.]

A single dose of 128 μg. vitamin A acetate was given orally to 45 rats depleted of vitamin A. At 7 time intervals between 1 and 24 hr., rats were killed and the liver, kidneys and plasma were analysed for vitamin A. Within 1 hr. the plasma value for vitamin A rose to 17 from 4 μg. per 100 ml. The maximum concentration occurred after 9 hr. with a value of 42 μg. per 100 ml., and after 24 hr. the level had fallen to 32. Vitamin A appeared in the liver after between 2 and 4 hr. Maximum total deposition was 46 μg. after 6 hr., and the same value was maintained throughout the 24 hr. Vitamin A appeared in the kidneys between the 6th and 9th hr. and after 24 hr. had reached a total of 3.3 μg.

In a second experiment 100 μg. vitamin A acetate were given to each of a number of rats, and at 18 time intervals ranging from 2 hr. to 30 days rats were killed and the liver and kidneys were analysed for total vitamin A. Maximum deposition in the liver was 20 μg.; it occurred after 6 hr. The value remained constant for about 4 days after which it decreased and reached 3.3 μg. after 30 days. Deposition in the kidneys reached a maximum of 7 μg. between the 14th and 23rd day and by the 30th the total had fallen to 3.1 μg. A nearly linear relation was found between hepatic and kidney vitamin A when, 23 to 30 days after treatment, the liver reserves were nearly used up.

In a third experiment rats with an initial hepatic reserve of 625 μg. were given a diet deficient in vitamin A. After 12 days the liver vitamin A had fallen to 174 μg., by 29 days to 79.3 μg. and by 54 days to 7.4 μg. The kidneys content remained fairly constant at about 20 μg. for the first 29 days but fell to 6.1 by the 54th day. Plasma vitamin A behaved in the same way with a concentration per 100 ml. of about 33 μg. for the first 29 days and of 9.0 by the 54th day.

An identical experiment with rats which had initial liver reserves of 62 μ g. of vitamin A gave a similar relationship but the liver reserves fell less rapidly during the early stages.—R. J. Ward.

SQUIBB, R. L., GUZMÁN, M. and SCRIMSHAW, N. S. Retención de la carotina y de la riboflavina y niveles séricos de vitaminas en ratas carentes de vitamina A alimentados con cuatro forrajes, achiote y aceite de palma africana. [Retention of carotene and riboflavin and serum levels of vitamins in vitamin-A-deficient rats fed on four forages, achiote and African palm oil.] *Bol. Ofic. sanit. panamer.*, 1953, *Suppl.* 1, 62–68. [Inst. Agropecuario Nac., Guatemala.]

Vitamin-A-depleted white rats of the USDA strain were given diets containing dried desmodium (*Desmodium intortum*), dried Kikuyu grass (*Pennisetum clandestinum*), dried ramie (*Boehmeria nivea*), dried banana leaves, seeds of achiote (*Bixa orellana*), or African palm oil. Retention of carotenoids and riboflavin and serum values for protein, riboflavin, ascorbic acid, alkaline phosphatase, carotenoids, vitamin A and total tocopherols were estimated after 12 days on the test diets.

The results are presented in detail. Carotenoid retention from the materials, in the same order as above, was 57, 77, 41, 66, 44 and 65 per cent. of the amount ingested. Riboflavin retention in the same order was 77, 84, 80, 40, 69 and 68 per cent. In spite of the differences in retention, no great difference was found in the serum values for any constituent.

It is concluded that all the materials tested were good sources of vitamin A for the rat.

P. C. Jowsey.

BERNHARD, K., RITZEL, G. and STEINER, K. U. Über eine biologische Bedeutung der Gallenfarbstoffe. Bilirubin und Biliverdin als Antioxydantien für das Vitamin A und die essentiellen Fettsäuren. [On a biological significance of bile pigments. Bilirubin and biliverdin as anti-oxidants for vitamin A and the essential fatty acids.] *Helv. chim. Acta*, 1954,

37, 306–313. [Physiol. Chem. Inst., Univ. Basle.] English summary.

When rats with a fistula of the thoracic lymph duct were given 1000 μ g. vitamin A, analysis of the lymph showed that about 50 per cent. of the vitamin was absorbed within 24 hr. (Abst. 1498, Vol. 23); if a fistula was made also to the bile duct so that the bile was drawn off, absorption was only from 0.3 to 1.6 per cent., and of carotene 0 to 0.2 per cent. Administration of the natural bile of rats or pigs through a third fistula increased the absorption of vitamin A to about 20 per cent. Taurocholic acid given in the same way caused absorption of from 2.1 to 10 per cent. In other experiments colloidal aqueous suspensions of vitamin A were incubated *in vitro* with or without biliverdin or bilirubin. The bile pigments greatly retarded oxidation of the vitamin. Their presence also reduced the rate of peroxide formation when emulsions of linoleic acid were shaken with air.

KAISER, E., FRANCIS, Y. F. and KAGAN, B. M. Vitamin A metabolism in nephrectomized rats. *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 457–458. [Kunstadter Labs. Paediat. Res., Michael Reese Hosp., Chicago, Ill.]

Both kidneys were removed from adult male albino rats, and others were subjected to a sham operation. Three hr. later vitamin A was estimated in the blood by Bessey's method. Some of the animals were then given an aqueous dispersion of vitamin A alcohol at the rate of 6000 I.U. per lb. bodyweight, and vitamin A was estimated in the blood 3 and 24 hr. later, after which the rats were killed and vitamin A was estimated in their livers. The removal of the kidneys had no effect on the concentration of vitamin A in the blood of untreated animals, or on the values found 4 or 24 hr. after giving vitamin A, or on the stores accumulated in the liver. The concentration of urea in the samples of blood taken 6 and 27 hr. after nephrectomy was high, but it did not rise after the sham operation.—T. Moore.

SORENSEN, D. K., KOWALCZYK, T. and HENTGES, J. F. (Jr.) **Cerebrospinal fluid pressure of normal and vitamin A deficient swine as determined by a lumbar puncture method.** *Amer. J. Vet. Res.*, 1954, **15**, 258-260. [Dept. Vet. Sci., Univ. Wisconsin, Madison.]

Growing pigs, in which in the beginning the cerebrospinal fluid pressure ranged from 89 to 120 mm., were depleted of their reserves of vitamin A and were allotted to one of 4 groups. One group was given no supplement, and the others were given 10, 25 or 40 µg. carotene per kg. bodyweight daily. Before the supplements were given the cerebrospinal fluid pressure had risen to between 148 and 175 mm. At the end of the period with supplements the group given no supplement showed signs of severe deficiency and the cerebrospinal fluid pressure ranged from 212 to 220 mm. Pressure in the pigs receiving 10 µg. carotene rose to 160 mm. from about 152, but in the pigs receiving 25 or 40 µg. it fell by about 20 mm.

O'DONOGHUE, J. G. **Vitamin A deficiency in beef cattle in Alberta 1953.** *Canad. J. Comp. Med.*, 1954, **18**, 141-147. [Vet. Serv. Branch, Alberta Dept. Agric., Edmonton.]

Ten case histories of cows and sheep with presumed deficiency of vitamin A are presented [without corroborative evidence]. Most of the animals died; some that were treated responded to vitamin A. Inco-ordination and other abnormalities associated with the central nervous system were the most prominent signs. The affected animal was often found lying down with the neck extended, the head turned upwards, and the mouth dry; there might be running movements with the legs rigid, and spasms of the shoulder and neck muscles. In one there was acetonæmia. The animals had been reared on poor diets of such foodstuffs as oat straw, oat bundles, screenings or second-cut alfalfa hay.—I. M. Sharman.

LAMMING, G. E., SALISBURY, G. W., HAYS, R. L. and KENDALL, K. A. **The effect of incipient vitamin A deficiency on reproduction in the**
Vol. 24, No. 4

rabbit. 1. Decidua, ova and fertilization. 2. Embryonic and fetal development. *J. Nutrition*, 1954, **52**, 217-225; 227-239. [Dept. Dairy Sci., Univ. Illinois, Urbana.]

1. Female rabbits were kept for about 3 months on a diet deficient in vitamin A, composed mainly of cereal products, with and without liberal supplements of carotene. Some of the rabbits in each group were then mated with vasectomised bucks. After 30 hr. the abdomen was opened and the formation of decidua was induced by insertion of a thread through the lumen of one horn of the uterus. When the animals were killed after another 36 hr., no difference in the formation of decidua was found between the groups, but the number of corpora lutea was less in the animals not given carotene. Others of the rabbits were mated with normal bucks and their fertilised ova were obtained for microscopical examination by flushing out the oviducts with warm saline 40 hr. or 4 days after copulation. Nearly all the ova from the animals given carotene were developing normally, but from 25 to 33 per cent. of those from the animals given the deficient diet showed premature degeneration. Throughout the experiments the rabbits all remained free from any signs of acute deficiency in the eyes and coat. Presence of the desired degree of incipient deficiency was, however, confirmed at autopsy by biochemical tests which showed traces only of vitamin A in the blood plasma and liver of the animals not given carotene.

2. Forty-two female rabbits were given diets lacking vitamin A. An equal number received the same diet with supplement of vitamin A or a commercial diet containing adequate amounts of carotene. The animals were mated, and were killed from 10 to 28 days later. Observation was made of the number of pregnancies, corpora lutea, living fetuses and resorption sites. Of the animals given the unsupplemented diet only 21 became pregnant, against 32 not deprived. The average number of corpora lutea was about the same for the deprived and non-deprived. The average number of living fetuses was greater in the non-deprived. Thus, in rabbits killed after from 16 to 28 days of pregnancy, those deprived had on the average 1.9 living fetuses and 3.3 resorption sites, against 6.1 and 0.5 sites for the deprived. In the deprived animals the eyes of the fetuses were sometimes abnormal, and the placenta had a mottled appearance. The pregnant rabbits appeared to be healthy even when given no supplement, but their reserves of vitamin A were low, as was shown by biochemical tests on the blood plasma and liver.—T. Moore.

WATKINS, W. E. and KNOX, J. H. **A study of the supplemental feeding of carotene for range breeding cows during the precalving and calving period.** *J. Animal Sci.*, 1954, **13**, 490-495. [New Mexico Agric. Exp. Stat., State College.]

Fifty grade Herefords including aged cows and first-calving heifers were divided into 2 groups as evenly as possible. They were maintained on pasture in Southern New Mexico with an excellent stand of black grama, a grass known to retain its carotene content well during the winter. The tests were repeated each year from 1946 to 1953. From 4 weeks before calving each cow in the first group of 25 received 1 lb. cottonseed meal daily, the others 1½ lb. of a mixture of 23 parts dehydrated alfalfa meal, 70 parts cottonseed meal and 7 parts molasses. The energy and digestible protein of the supplements were about the same. Carotene was estimated in the alfalfa meal and samples of forage every 28 days. Blood samples taken on the same day from about 16 representative cows in each group were analysed for carotene and vitamin A. The first samples were taken about 15 March each year before calving and further samples were taken in April and May. Three values only for carotene in the forage were low, less than 6.4 mg. per lb.; they were not associated with low values for plasma carotene. The carotene in blood was usually low in March but rose as the

young pasture appeared. The plasma value for carotene in the group given cottonseed meal was above that found by other workers in cows and heifers producing normal calves. In the group given alfalfa meal it was not above that in the group given no extra carotene. The values for vitamin A in the blood of the 2 groups did not differ significantly.—I. M. Sharman.

GALLUP, W. D., THOMAS, O. O., ROSS, O. B. and WHITEHAIR, C. K. **Carotene and vitamin A metabolism in cattle and sheep on phosphorus-deficient rations.** *J. Animal Sci.*, 1953, **12**, 715-721. [Oklahoma Agric. Exp. Stat.]

Yearling steers which had been depleted of their reserves of P and vitamin A were given a ration with a high or a low P content and a supplement of carotene equivalent to about 10 times the daily requirement. The steers receiving the low-P ration had consistently higher values for carotene in the plasma. At the time of slaughter the plasma of those having the low-P diet had on the average 119 µg. carotene per 100 ml., and those having the high-P diet had 76 µg. The respective plasma values for vitamin A were 17 and 22 µg. per 100 ml. The carotene and vitamin A values for the liver in the two groups were similar.

In a similar experiment with lambs, those having the low-P diet had higher values for vitamin A in the blood plasma throughout the experiment. At slaughter the values were 20.4 µg. per 100 ml. for those having the low-P diet and 18.2 for those having the high-P diet. The vitamin A content of the liver was 13.2 and 11.8 µg. per g., respectively.—R. J. Ward.

HANSEN, H. M., PORTER, G. H., JOHNSON, R. E., EATON, H. D., BEALL, G. and MOORE, L. A. **Effect of form of alfalfa when fed as the sole source of roughage to Guernsey cows on the carotenoid and vitamin A content of milk.** *J. Dairy Sci.*, 1954, **37**, 311-316. [Animal Indust. Dept., Storrs Agric. Exp. Stat.]

Guernsey cows were divided into 6 groups of 3. The 3 cows within a group were fed separately on

N.A. and R., October 1954

one of 3 forms of alfalfa in an experiment of double change-over design. The 3 forms, artificially dried and chopped, artificially dried and pelleted, and field-cured and field-baled, were each given for 40 days. Their respective carotenoid contents were approximately 31, 28 and 4 mg. per lb., and the daily carotenoid intakes were 801, 717 and 96 mg. per cow. The content of the milk in μg . per 100 ml. was for carotenoids 61, 42 and 47, and for vitamin A 19.8, 16.2 and 17.2. The proportion of the carotenoid intake which entered the milk was greatest with the field-cured and field-baled alfalfa.

LALITHA, K. R. and DASTUR, N. N. **Keeping quality of ghee. 2. Effect of storing butter and ghee on vitamin A content.** *Indian J. Dairy Sci.*, 1954, 7, 1-7. [Indian Dairy Res. Inst., Bangalore.]

In the preparation of ghee considerable loss of vitamin A occurred at the butter stage. Butter prepared from fresh milk had after 6 days 5 or 6 per cent. free fatty acids and there was a loss of from 12.5 to 19.4 per cent. of its vitamin A. Part of the loss was prevented by using boiled milk and by washing the butter before storage. Butter stored under water or in a 2 per cent. salt solution took about 5 times as long to lose this proportion of vitamin A. Samples of ghee exposed to mild diffused light lost from 44.0 to 82.6 per cent. of their vitamin A content after from 14 to 24 days' storage. If stored in the dark at room temperature with a small air-gap, the loss of vitamin A was from 12.5 to 36.1 per cent. after 120 days, but if the temperature was increased to 42° C. the loss was between 72 and 100 per cent. after about 85 days. Both cow and buffalo butter and ghee were examined, but the results did not show any certain difference in their storage properties.

SHROFF, N. B., NARAYANAN, K. M., ANANTAKRISHNAN, C. P. and SEN, K. C. **Studies on vitamin A in milk. 7. Effect of processing on the stability of vitamin A in fortified milk.** *Indian J. Dairy Sci.*, 1954, 7, 40-47. [Indian Dairy Res. Inst., Bangalore.]

Carotene and vitamin A are low in Indian milk, and fortification with synthetic vitamin A might well be beneficial. The effect of heat treatment on such added vitamin A was investigated. Portions of 6 samples of cow's and buffalo's milk were analysed for vitamin A and carotene before and after being pasteurised or boiled. Other portions of the same samples were fortified with vitamin A in fat-soluble and water-miscible form and were similarly investigated. Both carotene and vitamin A proved to be stable to the heat treatments. Cow's milk which averaged 2174 I.U.

vitamin A per lb. after fortification with 2739 I.U. fat-soluble vitamin A per 2550 ml. milk had values of 2165 and 2173 I.U. per lb. after pasteurisation and boiling, respectively. The average values of samples fortified with 5215 I.U. water-miscible vitamin A per 2550 ml. milk were 3178 before processing and 3172 and 3162 after. In other experiments the effect of the heat treatments on samples of skimmed milk, also fortified with water-miscible vitamin A, were investigated, and the vitamin was again found to be unaffected. In the process of khoa-making, however, 7.5 and 7.0 per cent., respectively, of the vitamin A and carotene content of whole milk disappeared. When milk fortified with both forms of vitamin A was used for this purpose the loss of the vitamin was about the same as when unfortified milk was employed. Throughout the experiments buffalo's milk behaved like cow's milk.—I. M. Sharman.

4350

ABDULLAH, M. M., MORCOS, S. R. and SALAH, M. K. **Content of vitamin A₂ in some Nile fishes.** *Biochem. J.*, 1954, 56, 569-571. [Dept. Biochem., Fac. Med., Univ. Alexandria.]

The liver oils of several different kinds of Nile fish were examined for vitamins A₁ and A₂ and neovitamin A₂. Estimations were made with the SbCl₃ reaction and by ultraviolet spectrophotometry after chromatography on weakened alumina. Neovitamin A₂ was estimated by the maleic anhydride method. Of the 15 fish examined only 2 contained appreciable amounts of vitamin A₁; their liver oil contained from 320 to 600, and 4000 μg . per g. Spectrophotometric examination showed that vitamin A₂ also was present. The other 13 liver oils gave ultraviolet spectra characteristic of vitamin A₂. Their potency ranged from 840 to 70,000 μg . per g. Six of the 13 contained the *neo* form in amounts ranging from 6.2 to 22.5 per cent.

MCCOLLUM, J. P. **Effects of light on the formation of carotenoids in tomato fruits.** *Food Res.*, 1954, 19, 182-189. [Dept. Hort., Coll. Agric., Univ. Illinois, Urbana.]

Green tomatoes exposed to sunlight often had a poor colour, owing to the low lycopene content caused by the high temperature. At a lower temperature light increased the amount of lycopene in tomatoes off the plant. Light had no further effect on the lycopene content after the chlorophyll had disappeared. The carotene content was increased by sunlight even at high temperatures. Chlorophyll in mature tomatoes stored in absence of oxygen and light failed to decompose. Decomposition in light but in absence of oxygen appeared to be brought about by the oxygen produced in photosynthesis.—V. H. Booth.

VITAMIN D

4352

WEI, L., PYKE, R. E. and PARRISH, D. B. **Ash content of chick beak for vitamin D assays.** *J. Agric. Food Chem.*, 1954, **2**, 568-569. [Kansas Agric. Exp. Stat., Manhattan.]

Chicks were prepared, fed, and selected, according to the A.O.A.C. (1950) method. In 7 trials, groups of from 6 to 27 chicks received for 12 or 21 days amounts graded from 0 to 25 I.C.U. vitamin D per 100 g. feed as the U.S.P. XIV reference oil. Ash was estimated separately in the "hard bone" of the upper beak [presumably the anterior part of the premaxilla], the bones of the lower beak cut at the root of the tongue, the tibia and the toe bones.

In the 21-day-test, in response to increasing dose, the upper and lower beak bones showed a slightly steeper rate of increase in the percentage ash than the tibia; both beak and tibia gave a more sensitive response than toes. Duplicate estimations gave satisfactory results. In the 12-day test, the responses were less well graded.

The beak is much easier to prepare than the tibia, and as it gave equally reliable results its use is recommended.—E. M. Hume.

ROSS, E. and YACOWITZ, H. **Effect of penicillin on growth and bone ash of chicks fed different levels of vitamin D and phosphorus.** *Poultry Sci.*, 1954, **33**, 262-265. [Ohio State Univ., Columbus.]

Chicks were fed on a basal rachitogenic diet containing 0.33 per cent. inorganic P and 0.6 per cent. total P, with or without supplements of vitamin D and penicillin. In one experiment the inorganic P content was raised to 0.54 per cent. by the addition of defluorinated rock phosphate. In the absence of vitamin D, penicillin significantly improved growth when dietary P was high, but not when it was low. When the diet was supplemented with amounts of vitamin D greater than 4 I.U. per 100 g., penicillin significantly increased tibia ash. On a low-P ration, the percentage of fat in the tibia increased with increase in the amount of vitamin D given. With the lower amounts of vitamin D, penicillin had no consistent effect on the fat content of the tibia, but with the higher amounts, penicillin increased tibia fat.—E. M. Cruickshank.

4359

WEITS, J. **The antivitamin D factor in roughages.** *Netherlands J. Agric. Sci.*, 1954, **2**, 32-36.

N.A. and R., October 1954

[Lab. Animal Physiol., Agric. Univ. Coll., Wageningen.]

Vitamin D was separated from the rachitogenic substance in dry grass and hay by chromatography [no details]. Fractions of the unsaponifiable residue of the grass fat, with addition of fixed amounts of vitamin D, were tested on rachitic rats, with radiography of the bones as criterion, to ascertain the content of rachitogenic substance. A fraction was obtained which contained all the vitamin D but not the rachitogenic substance. The last was present chiefly in the carotene fraction; the fraction containing xanthophylls was inactive.

The method was applied to routine estimation of roughages. In hay dried in windrows or cocks or on tripods the vitamin D content ranged from 1005 to 1375 I.U. per kg., and there was little

increase after chromatography, showing the absence of rachitogenic substance. In artificially dried grass the values ranged from 270 to 1150 before chromatography, and from 595 to 1790 after it; the amount of rachitogenic substance was, therefore, considerable. The results were in accordance with the finding of Grant (Abst. 1730, Vol. 24), that carotene is the rachitogenic substance. The rachitogenic substance was not a phytosterol precipitable with digitonin.—E. M. Hume.

THEOPOLD. Tierexperimentelle Untersuchungen über den Vitamin D-Gehalt ultraviolett-bestrahlter Milch. [Animal experiments on the vitamin D content of milk irradiated with ultraviolet light.] *Monatsschr. Kinderheilk.*, 1954, 102, 176-177. [Marburg.]

VITAMIN E

4361

SINGSSEN, E. P., MATTERSON, L. D., KOZEFF, A., BUNNELL, R. H. and JUNGHER, E. L. **Studies on encephalomalacia in the chick. 1. The influence of a vitamin E deficiency on the performance of breeding hens and their chicks.** *Poultry Sci.*, 1954, 33, 192-201. [Dept. Poultry Husb., Storrs Agric. Exp. Stat., Univ. Connecticut.]

During a preliminary period of 3 weeks, 6 groups of 25 Barred Plymouth Rock pullets received a basal ration low in vitamin E, and then for a further 9 months two groups received no supplement, two groups received an addition of 2 per cent. of a vitamin A and D oil [kind not stated], and two groups received B and other vitamins. One group in each pair of groups received 13.62 mg. α -tocopheryl acetate per lb. diet. Complete records of egg production, mortality, fertility and hatchability were kept.

Low values for tocopherol were found in the blood of birds whose diet was not supplemented with vitamin E; egg production and adult mortality were not affected, but the addition of tocopherol gave a highly significant increase in fertility. Histological examination of the brains of 21-day-old, pipped, embryos and day-old chicks revealed several with encephalomalacia. Chicks, hatched from the breeding hens without vitamin E and reared on a diet low in vitamin E with 2 per cent. of fish oil, regularly showed mortality rates between 33 and 67 per cent. Mortality was generally due to encephalomalacia and was prevented when tocopherol was added to the diet. Of 104 chicks with encephalomalacia, 67 were male and 37 female, a sex ratio of approximately 2 to 1. Addition of tocopherol to breeder diets with small amounts of vitamin A and D oil re-

duced mortality from encephalomalacia but did not entirely prevent it when the chicks were given the ration low in vitamin E with added oil. To secure the lowest rate of mortality it was necessary to add both tocopherol and a complex mixture of vitamins to the breeder diet.—I. M. Sharman.

LEHR, D., CHURG, J. and MILORA, R. **Influence of alpha-tocopherol upon development of cardiovascular necrosis and hypertension in the rat.** *Proc. Soc. Exp. Biol. Med.*, 1954, 85, 615-624. [Dept. Physiol., New York Med. Coll., Flower and Fifth Avenue Hosp., New York.]

Ten-month-old rats were given a single massive intraperitoneal injection of sodium acetyl sulphathiazole, which caused acute kidney block. Groups were then kept on a basal diet which supplied daily 0.8 mg. tocopherol, or up to 20 mg. *dl*- α -tocopheryl acetate, mixed with the diet or given separately by stomach tube. During the next few weeks systolic blood pressure was recorded, and the organs of animals which died or were killed were examined histologically. The massive dose of tocopherol did not control the blood pressure or prevent the development of disseminated muscular necrosis. On the contrary, the tocopherol appeared to increase the severity of the lesions in the aorta, coronary arteries and stomach. Even in rats which had not been subjected to kidney block tocopherol caused moderate hypertension.—T. Moore.

4366

VISWANATHA, T., GANDER, J. E. and LIENER, I. E. **Interrelation of fat, carbohydrate and vitamin E in the diet of the growing rat.** *J. Nutrition*, 1954, **52**, 613–626. [Dept. Agric. Biochem., Univ. Minnesota, St. Paul.]

The growth-promoting properties of vegetable and animal fat, as represented by maize oil and butterfat, were compared in numerous complicated experiments with weanling rats. The carbohydrate component of the diet was sucrose or lactose, supplements of vitamin E were given or withheld, and in some groups a deficiency of vitamin E was induced by giving phthalylsulphathiazole, alone or in combination with tri-*o*-cresyl phosphate.

When a diet containing lactose was given without a supplement of vitamin E to weanlings of unknown dietary history, butterfat produced better growth than maize oil, but the difference disappeared when a daily supplement of 0.3 mg. α -tocopherol was given. When the diet contained sucrose growth was better than when it contained lactose, and no difference was apparent with change of the fat or with and without tocopherol.

Other rats were given diets without vitamin E and containing lactose or sucrose and either maize oil or hydrogenated vegetable oil, and vitamin E was estimated in the blood of animals killed at intervals up to 5 weeks. In the group given lactose and maize oil the value fell from 225 μ g. per 100 ml. after 1 week to 87 after 5 weeks; in the other groups the values after 5 weeks remained at from 310 to 370.

Young rats which had been depleted by feeding them for 2 weeks on a diet containing tri-*o*-cresyl phosphate and phthalylsulphathiazole grew better on a diet containing sucrose or lactose when given butterfat than when given maize oil. The inferior growth with maize oil and lactose could be brought nearer to the growth with butter-

fat by adding vitamin E; the better growth with sucrose was not influenced by vitamin E.

In young from mothers given a diet deficient in vitamin E, maize oil was more protective than butterfat against haemolysis in the test with dialuric acid, whether the diet contained lactose or sucrose. A daily supplement of 0.3 mg. vitamin E gave full protection, irrespective of the nature of the fat or carbohydrate.—T. Moore.

FREY, J. and HOFFMANN, G. Untersuchungen am isolierten Warmblüterherzen über die Wirkung des *dl*- α -Tokopherol. [Studies with the isolated heart of warm-blooded animals of the effect of *dl*- α -tocopherol.] *Arch. exp. Pathol. Pharmacol.*, 1954, **221**, 477–481. [Klin. Med., Univ. Freiburg i. Br.]

The addition of sodium *dl*- α -tocopheryl phosphate to the Ringer solution used for perfusing isolated beating guineapig hearts had different effects according to the concentration. At from 1 to 5×10^{-7} the strength of the contractions, but not the frequency, was increased. There was no reduction in the circulation through the coronary system. At 1×10^{-6} the amplitude of the heart beat, its frequency and the coronary circulation were all reduced, and at 1×10^{-5} the heart stopped beating. With a concentration of 5×10^{-7} the preliminary increase in the amplitude of the heart beat was followed after 30 min. by a reduction, which indicated that the effect of the tocopherol was cumulative. Small doses of tocopherol constricted the coronary vessels in hearts which had stopped beating.—T. Moore.

FREY, J. Über Stoffwechselwirkungen von α -Tokopherolen, im besonderen untersucht an der Niere. [Metabolic effects of α -tocopherols, in particular on the kidney.] *Arch. exp. Pathol. Pharmacol.*, 1954, **221**, 466–476. [Klin. Med., Univ. Freiburg i. Br.]

The respiration of slices of rat's kidney suspended in 0.85 per cent. saline was reduced by 20 per cent. by the addition of 5 mg. sodium-*dl*- α -tocopheryl phosphate per ml. With lower concentrations down to 0.5 μ g. per ml. graded reductions in respiration occurred. The tocopherol reduced respiration also in heart, muscle, brain and embryo, but in liver respiration was increased by 25 per cent., though it was partly or completely inhibited by larger amounts, 50 mg. per ml. or more. Pentamethyl-6-hydroxy-chroman phosphate had a similar action. Tocopherol decreased the tiring of frog's muscle as tested by electrical stimuli, and partly counteracted the toxicity of monoiodoacetic acid and cyanide.

In 3 human volunteers daily doses of from 170 to 200 mg. *dl*- α -tocopheryl acetate caused increases of from 10 to 57 per cent. in the volume of urine excreted. In a large group of mice daily injections of 10 mg. sodium tocopheryl phosphate per kg. bodyweight increased the volume of urine by 108 per cent., and the amounts of NaCl and urea excreted by 96 and 27 per cent., respectively; the sp. gr. of the urine was reduced. The effect of injections of sodium tocopheryl phosphate on the diuresis of mice which were given excess of water, orally or by injection, varied between individuals.

T. Moore.

FREY, J. Über den Einfluss von *dl*- α -Tokopherol auf den fermentativen Phosphatstoffwechsel der Tubuluszellen der Rattenniere. [Effect of *dl*- α -tocopherol on fermentative phosphate metabolism of the tubule cells of the rat kidney.] *Arch. exp. Pathol. Pharmacol.*, 1954, **221**, 482-488. [Klin. Med., Univ. Freiburg i. Br.]

The respiration of slices of rat kidney cortex, and the production of ammonia by them, were decreased by the addition of sodium α -tocopheryl phosphate to the suspension. The phosphatase activity and adenosinetriphosphatase activity also of the homogenised tissues were decreased by sodium tocopheryl phosphate. Injection of 3 or 10 mg. of *dl*- α -tocopheryl acetate into rats daily for 4 or 5 days caused the adenosinetriphosphate content of the kidney cortex to be reduced by 21 or 40 per cent. and phosphocreatine to be reduced by 60 or 70 per cent.—T. Moore.

SHARMAN, G. A. M. Muscular dystrophy of beef calves in the North of Scotland. *Vet. Rec.*, 1954, **66**, 275-279. [North of Scotland Coll. Agric., Inverness.]

A full description is given of a disease of suckled beef calves which occurs in the North of Scotland when housed cattle are first put to grass in early summer. It has been established that the disease is a muscular dystrophy, characterised clinically by bilaterally symmetrical stiffness, especially of the shoulder region. Sudden death may occur from degeneration of the myocardium. Some affected animals have difficulty in breathing, owing to dystrophy of the intercostal muscles or the diaphragm. The disease is variable in its incidence from year to year. Exercise appears to precipitate the appearance of signs.

The affected muscle fibres become swollen and more highly eosinophilic. Hyaline degeneration follows and the tissue becomes invaded by a mass of nuclei, perhaps of sarcolemmal origin. Such muscles have a low creatine content, and the liver tocopherol content is also low.

Roughly 60 per cent. of calves showing stiffness recover slowly without treatment if kept warm and confined. But treatment with α -tocopherol acetate by mouth, in doses of 600 mg. followed by 200 mg. daily, will induce recovery within a few days.

The disease can be prevented by ensuring that in-calf cows receive adequate amounts of vitamin E by mouth, or by giving calves this vitamin from birth. Grass is a good source of the vitamin, as are the kales and wet distiller's grains.

The anti-vitamin-E effect of unsaturated fatty acids appears to have been responsible for a few cases of the disease, which has been observed in bulls given cod liver oil.—W. A. Greig.

SLINGER, S. J., PEPPER, W. F. and MOTZOK, I. Interrelationship between vitamin E and phosphorus in preventing perosis in turkeys. *J. Nutrition*, 1954, **52**, 395-403. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

Twelve groups of turkey chicks, each of 20 males and 20 females, were reared on starting and growing basal diets which included cereal products, soyameal, fishmeal, and meatmeal, manganese, and vitamins except for vitamin E. The total amount of inorganic P was adjusted to be 0.3, 0.5 or 0.7 per cent., and each proportion of P was given alone or with 0, 2.5, 5.0 or 7.5 I.U. *d*- α -tocopheryl acetate per lb. mash. The weight reached by the birds after 24 weeks was slightly greater with 0.5 or 0.7 per cent. P than with 0.3 per cent., but the amount of vitamin E did not affect growth. Perosis, shown by enlargement of the hock joints and bowing of the legs, was seen in males but not in females. The greatest incidence was 52.6 per cent. in the group given 0.3 per cent. P without vitamin E. Raising the percentage of P to 0.7 without giving vitamin E decreased the incidence of perosis to 23.8 per cent. A tocopherol allowance of 7.5 I.U. per lb. combined with 0.3 per cent. P reduced the incidence to 20 per cent. With 0.7 per cent. P and 5 or 7.5 I.U. vitamin E per lb. feed, perosis was prevented in all the birds. With the other combinations of P and tocopherol, there was intermediate incidence of perosis.

ANDERSON, G. C., HARE, J. H., BLETNER, J. K., WEAKLEY, C. E. (Jr.) and MASON, J. A. **A hemorrhagic condition in chicks fed simplified rations.** *Poultry Sci.*, 1954, **33**, 120-126. [Dept. Animal Husb., W. Virginia Agric. Exp. Stat., Morgantown.]

Chicks maintained on wire floors and given a ration of yellow maize, solvent-extracted soya bean meal, minerals, vitamins A and D, riboflavin and vitamin B₁₂ showed haemorrhages in the breast and leg muscles, in the brain, and subcutaneously in the wings and legs. The blood clotting time was prolonged. Inclusion in the diet of menadione, alfalfa meal or fresh or dried droppings reduced clotting time and mortality from haemorrhage. Inclusion in the diet of penicillin, sulphaquinoxaline or a commercial coccidiostat, or penicillin combined with any one of these, did not reduce the haemorrhages.—E. M. Cruickshank.

4373

SWEET, G. B., ROMOSER, G. L. and COMBS, G. F. **Further observations on the effect of sulphaquinoxaline, *p*-aminophenylarsonic acid, and oxytetracycline on blood clotting time of chicks.** *Poultry Sci.*, 1954, **33**, 430-432. [Dept. Poultry Husb., Univ. Maryland, College Park.]

Chicks were fed for 4 weeks on a basal ration containing no alfalfa meal or added vitamin K, with or without supplements of sulphaquinoxaline, *p*-aminophenylarsonic acid and oxytetracycline (terramycin) given separately or together. On the basal ration alone, blood clotting time was normal. Addition of 0.03 per cent. sulphaquinoxaline or 0.03 per cent. *p*-aminophenylarsonic acid or a combination of them with 0.02 per cent. oxytetracycline prolonged blood clotting time, but it was restored to normal by supplementing the diet with 1 or 5 per cent. dehydrated alfalfa or 0.36 mg. menadione per lb. Blood Ca was not affected by the drugs.—E. M. Cruickshank.

4374

HOSKIN, F. C. G., SPINKS, J. W. T. and JAKES, L. B. **Urinary excretion products of menadione (vitamin K₃).** *Canad. J. Biochem. Physiol.*, 1954, **32**, 240-250. [Dept. Chem., Univ. Saskatchewan, Saskatoon.]

Adult male albino rats received intramuscular injections per kg. bodyweight of from 3.8 to 11.0 mg. radio-active vitamin K₃ in sesame oil. Urine

was collected from 10 to 20 hr. after each injection; the radio-active products were separated by paper chromatography and identified by absorption spectra and chemical analysis.

From 20 to 40 per cent. of the administered radio-activity was excreted during the 20 hr., less than 10 per cent. in the following 20 hr. At least 2 products were detected. Incubation with glucuronidase showed that one was the diglucuronide; acid hydrolysis showed that the other was a mono-sulphate of vitamin K₃. The latter was not hydrolysed by arylsulphatase. The excretion of the 2 products increased with the amount of vitamin K₃ given. A third radio-active product was detected at the lower levels of dosage. It was easily hydrolysed. Glucuronic acid was not recovered; the findings for sulphate ion were indefinite. The excretion of the third radio-active product did not increase. Little or no vitamin K₃ as such was found in the urine.

The same products were found after administration of vitamin K₃ in the urine of an adult guinea-pig and of a rat that had received dicoumarol orally for 6 days.—V. R. Jackson.

4375

HINZ, C. F. and HARRIS, J. O. **The effect of certain vitamin K compounds upon the respiration of *Saccharomyces cerevisiae*.** *Arch. Biochem. Biophys.*, 1954, **48**, 261-266. [Dept. Bacteriol., Kansas Agric. Exp. Stat., Manhattan.]

The rate of respiration at 30° C. was estimated for young, active cells of *Saccharomyces cerevisiae* grown in a glucose medium with different amounts of vitamin K₃ (2-methyl-1:4-naphthaquinone) or its diphosphate or the K salt of vitamin K₅ (2-methyl-4-aminonaphthol hydrochloride). Vitamin K₃ as the phosphate had little effect on respiration, showing that the phosphate group was stable in the experimental conditions. Vitamin K₅ and vitamin K₃ inhibited respiration, the former more than the latter, which showed that the toxicity was not necessarily due to the unsaturated ketone structure of the latter. At higher concentrations of the vitamins, production of CO₂ was inhibited more than uptake of O₂.

With the Ca salt of fructose 1:6-diphosphate or Na pyruvate or ethanol as substrate, both vitamins inhibited uptake of O₂ and production of CO₂ in aerobic conditions. There was no evidence that any single enzymic change was affected by the inhibition.—V. R. Jackson.

VITAMIN B COMPLEX: GENERAL

4376

JONES, A., TAYLOR, M. P. and GORE, D. N. **The detection of the vitamins of the B group by means of small circular chromatograms.** *Chem. and Indust.*, 1954, No. 16, 461-462. [Beecham Research Laboratories, Ltd., Brookham Park, Betchworth, Surrey.]

Detection of nicotinic acid or nicotinamide or both in amounts as small as 0.01 μ g. was achieved by putting 0.005 ml. solution on a circular filter paper cut to fit a Petri dish, and leaving the chromatogram for 1 hr. according to the method of Giri and Rao (Abst. 1500, Vol. 22) with butanol and ammonia, or butanol and water, air drying and then placing the paper for 15 min. on the surface of nutrient agar seeded with *Lactobacillus arabinosus*. The plate was incubated at 30° or 37° C. for 4½ hr. or more to give well defined growth zones. The method has been applied to natural products and to mixed vitamin preparations.

4377

HEYNDRIKX, A. **Paper chromatography of choline and the vitamins B₁, B₂, niacin, and niacinamide. Preparation of radioactive choline acetate and study of its hydrolysis.** *J. Amer. Pharm. Assoc.*, 1953, 42, 680-681. [Coll. Pharm., Univ. Minnesota.]

With paper chromatography and *n*-propanol and HCl as solvent, vitamin B₁, riboflavin, nicotinic acid and nicotinamide (free or associated with choline) were separated qualitatively. A spot test for each is described.

Radio-active choline acetate was prepared. After 24 hr. of ordinary atmospheric interference, it was hydrolysed to the extent of 54 per cent. and, after 3 days, of nearly 61 per cent. It was completely hydrolysed in an aqueous medium within a few seconds.—K. H. Coward.

4378

SILIPRANDI, N., SILIPRANDI, D. and LIS, H. **Separation and determination of vitamin B₆ group (pyridoxine, pyridoxal, pyridoxamine, pyridoxal phosphate and pyridoxamine phosphate). Separation by paper electrophoresis of riboflavin (riboflavin, FMN and FAD) and of nicotinamide (nicotinamide, DPN and TPN) groups.** *Biochim. biophys. Acta*, 1954, 14, 212-218. [Inst. Biochem., Univ. Upsala.] French and German summaries.

Separation of the substances of the vitamin B₆ group was by electrophoresis and spraying with diazotised *p*-aminoacetophenone. The colour of the spots ranged from pink to yellow, and was

stable; there was no breakdown of the esters. Methods are described for making the estimation quantitative.

Riboflavin and its coenzymes were separated by the same methods of electrophoresis on paper. The spots were located by their bright yellow fluorescence in ultraviolet light.

Nicotinamide and its coenzymes also were separated; di- and triphosphopyridine nucleotides were converted to the dihydro-forms after electrophoresis, by spraying with Na₂S₂O₃ and NaHCO₃, when their spots showed a feeble fluorescence in ultraviolet light; nicotinamide and its compounds showed dark spots.

The three methods listed above could be applied to detection of all the substances in presence of one another. A "Mineral light" was used first; it showed all the spots and identified those due to riboflavin compounds by their yellow fluorescence; their specific reactions could then be applied to the vitamin B₆ and nicotinamide groups.

V. R. Jackson.

4379

REID, M. E. **Nutritional studies with the guinea pig. B-vitamins other than pantothenic acid.** *Proc. Soc. Exp. Biol. Med.*, 1954, 85, 547-550. [Lab. Biochem., Nat. Inst. Health, Pub. Health Serv., U.S. Dept. Health, Bethesda, Md.]

Groups of guineapigs from 2 to 4 days old received for 6 weeks a basal diet previously described by Reid and Briggs (Abst. 3515, Vol. 24) from which single vitamins were omitted.

The signs of deficiency of vitamins B₁ and B₆, choline and folic acid are described; weight gains and the numbers of survivors were less than in groups having the complete diet. Retardation of growth occurred when nicotinic acid or riboflavin was omitted, but there were no specific signs of deficiency. Some of the survivors grew well and might have lived indefinitely.

There was no significant difference in weight of groups receiving a complete diet or a diet without *p*-aminobenzoic acid, inositol, biotin or vitamin B₁₂, although it is thought that those vitamins were necessary for maximum growth. When only 3 μ g. folic acid were included per kg. diet, there was some response to *p*-aminobenzoic acid, but in the presence of 10 μ g. folic acid per kg. it had no effect.—V. R. Jackson.

4380

STOERK, H. C., KNOWLTON, A. I. and LOEB, E. N. **Failure of liver feeding to counteract cortisone effects other than growth inhibition.** *Proc.*

Soc. Exp. Biol. Med., 1954, **85**, 627-631.
[Merck Inst. Therap. Res., Rahway, N.J.]

Experiments on rats showed that liver powder added to the diet prevented the inhibition of growth by cortisone given orally, but had no effect when the cortisone was given subcutaneously. In adrenalectomised rats liver powder was ineffective whether the cortisone was given orally or parenterally. In intact rats not given liver powder the growth-inhibiting effect of cortisone was greater when it was given parenterally than orally. Liver powder had no effect on the hypertensive action of cortisone, or on the rise in blood sugar and liver glycogen which follows cortisone administration. Serum sodium studies suggested that the supplement of liver had no effect on the absorption of cortisone.—L. Wills.

ALLISON, J. B., WANNEMACHER, R. W. (Jr.) and MIGLIARESE, J. F. **Diet and the metabolism of 2-aminofluorene.** *J. Nutrition*, 1954, **52**, 415-425. [Bur. Biol. Res., Rutgers Univ., New Brunswick, N.J.]

Dogs received diets with no protein, or with sufficient to maintain nitrogen equilibrium in a normal dog, or with high protein content, and with vitamins in amounts adequate for normal growth of young dogs. Riboflavin or pantothenate was omitted from some of the diets, and then given in increased amounts. All dogs received orally 30 mg. of the carcinogen 2-acetylaminofluorene or 2-aminofluorene per kg. bodyweight 2 and 1 week, respectively, before the end of the time on a given diet. Urine was collected for the 3 days after each treatment and diazotisable amines were estimated.

In the urine an acid- and ether-soluble amine, identified as 2-aminofluorene, and an ether-soluble conjugated amine, identified as 2-acetylaminofluorene, increased with the protein content of the diet. There was no change in the amount of ether- and alkali-soluble amine. The amount of water-soluble, heat-labile amines excreted decreased with increasing protein content; it was greater with the free amine, possibly owing to the greater toxicity of the latter. Excretion of free and conjugated amines increased with the content of riboflavin or pantothenate in the diet; reduction of the riboflavin and protein intake increased the heat-labile amine fraction. It is suggested that the protective effect of diets high in protein and vitamins may be due to their promoting oxidation of the carcinogens by the liver.

The tests showed that the degree of conjugation of amines could not be estimated from the degree of diazotisation before and after hydrolysis of urine.—V. R. Jackson.

KIMBEL, K. H., HEISE, E. and KÖNIG, H. Untersuchungen über enterale Antibiose bei der Ratte. [Studies on intestinal antibiotics in the rat.] 1. Veränderungen der Glucosebelastungskurve. 1. **Changes in the glucose tolerance curve.**

HEISE, E. and KIMBEL, K. H. 2. Veränderungen der Haut und des Haarkleides. [2. **Changes in the skin and hair.**] *Ztschr. ges. exp. Med.*, 1954, **123**, 265-278; 326-331. [Med. Poliklin., Univ. Würzburg.]

1. After preliminary studies on rats of normal fasting values for blood sugar and response to a large dose of glucose, the effect was tested of giving terramycin, streptomycin or aureomycin in oral doses of 20 mg. daily. After 18 to 22 days' treatment, the blood sugar curve in response to administration of glucose was abnormally flat. Normal absorption of sugar was restored by administration of the vitamin B complex or of vitamin B₁₂ alone, but not of folic acid alone.

2. When administration of terramycin or aureomycin was continued for more than 20 days signs of vitamin deficiency appeared, including skin lesions on the ears, nose and tail and poor, staring fur; finally the skin lesions became very severe and some rats died. Oral doses of vitamin B complex produced some improvement but injection of pyridoxine alone gave the most satisfactory cure of the whole condition. Injection of vitamin B₁, riboflavin or vitamin B₁₂ caused little or no change, and with nicotinic acid alone the skin condition deteriorated.—A. M. Copping.

4383

KESLER, E. M. **Effect of terramycin fed to Holstein calves on growth, in-vitro cellulose digestion and B-vitamin synthesis.** *J. Animal Sci.*, 1954, **13**, 10-19. [Pennsylvania Agric. Exp. Stat.]

Healthy male Holstein calves aged from 1 to 4 days received a milk replacement diet described by Williams and Knodt (Abst. 1117, Vol. 20) with or without 2 g. crystalline terramycin per 100 lb. replacement diet. During the seventh week, half of the animals receiving terramycin had it removed from the diet and half of those not receiving the drug had it added to the diet. A group of controls received milk throughout the test. All calves were offered up to 5 lb. calf starter diet daily and hay to appetite. Samples of rumen contents were obtained after 6, 12 and 16 weeks. Estimations were made of vitamin B₁ and riboflavin and of cellulose digestive activity in an artificial rumen. Bodyweight and height at withers were measured at weekly intervals.

During the first 8 weeks the growth of the calves receiving terramycin or milk was signifi-

N.A. and R., October 1954

cantly greater than of those without terramycin. After 8 weeks there was no significant difference in growth rate between those with and without antibiotic. Administration of antibiotic after the seventh week to those previously without it had no effect on growth from 8 to 12 weeks but caused it to be fairly rapid from 12 to 16 weeks. Terramycin increased consumption of calf starter diet but not of hay.

There was no difference in the vitamin B₁ content of rumen fluid, but that of riboflavin was slightly higher in calves given terramycin at the start. When the terramycin was started at the seventh week it had no effect on the riboflavin concentration. Terramycin had no adverse effect on rumen synthesis of vitamin B₁ or riboflavin.

Cellulose digestion by rumen liquid in an artificial rumen was poorer for calves receiving terramycin, 24.2 per cent. compared with 67.4 per cent. for those without. Administration of terramycin by capsule for 3 days to calves previously without it significantly reduced the digestive power to 12.3 per cent. from 49.5; omission caused a return to the former state. The results provided evidence that the antibiotic inhibited the micro-organisms responsible for cellulose breakdown.—V. R. Jackson.

BARNHART, C. E., CATRON, D. and CULBERTSON, C. C. **The effect of rations on selected vitamin content of sows' milk.** *J. Animal Sci.*, 1954, **13**, 375-382. [Dept. Animal Husb., Iowa Agric. Exp. Stat., Ames.]

Riboflavin, nicotinic acid and pantothenic acid were estimated microbiologically in milk from sows on the 2nd, 7th, 21st and 56th day of lactation. The sows were receiving all-vegetable or mixed animal and vegetable protein and, in some groups, supplements of alfalfa meal with or without extra meat scraps. Milk was readily obtained after injection of pituitrin or pitocin. Alfalfa meal increased the amount of all three vitamins in the milk but that of pantothenic acid was the only one significantly increased. Alfalfa meal and meat scraps caused a significant increase in the riboflavin content, but no significant increase in that of nicotinic acid or pantothenic acid.

LEE, F. A., BROOKS, R. F., PEARSON, A. M., MILLER, J. I. and WANDERSTOCK, J. J. **Effect of rate of freezing on pork quality. Appearance, palatability, and vitamin content.** *J. Amer. Dietetic Assoc.*, 1954, **30**, 351-354. [New York Agric. Exp. Stat., Cornell Univ., Geneva.]

Chops from *longissimus dorsi* muscles of 2 pig carcasses were frozen by plate contact at -50° F. for 1½ hr., or in a home freezer at 0° F. for 5½ hr., or in an insulated box in a home freezer at 0° F. for 19 hr. Samples were used immediately or after storage for 6 months at 0° F.

Samples were thawed and broiled to an internal temperature of 150° F. Total solids, ether extract, vitamin B₁, riboflavin, pantothenic acid and vitamin B₆ were estimated in three samples and in cooked unfrozen samples and in a raw frozen sample.

The rate of freezing and period of storage appeared to have no effect on the vitamin content. Vitamin B₆ was lower in the cooked samples. Differences in palatability, including flavour, appearance, odour, texture and juiciness, were not significant. Extremely slow freezing is not recommended, since the quality of the meat might be affected and changes due to micro-organisms could occur. To avoid such slow freezing, a large quantity of unfrozen packages should not be put at one time into a home freezer not adapted to deal with such quantities.—V. R. Jackson.

4391

JOSHI, S., MASTER, F. and MAGAR, N. G. Nutritive value of some Bombay fish. 1. Distribution of non-protein nitrogen extractives, and thiamin, riboflavin, and niacin. *Indian J. Med. Res.*, 1953, **41**, 431-439. [Dept. Biochem., Inst. Sci., Bombay 1.]

Vitamin B₁, riboflavin and nicotinic acid were estimated in the muscle of 24 species of Indian fish and in the livers and roes of 4 enzyme hydrolysis. Values for the vitamins were higher after than before acid hydrolysis. The results by acid hydrolysis were in general agreement with those of other workers and in $\mu\text{g. per g.}$ ranged from 0.1 to 1.1 for vitamin B₁, from 0.5 to 12.9 for riboflavin, and from 6.1 to 48.2 for nicotinic acid. Bombay duck was low in all the vitamins, but it is concluded that a liberal intake of fish would make a valuable contribution to the daily requirement.

In teleostean fishes N.P.N. was 10 to 11 per cent. of the protein N and in elasmobranchs 57 per cent. There was no difference between the 2 types in trimethylamine content. The rate of formation of trimethylamine depended on the species but was slowed by storage in the cold; degree of spoilage was comparable after 1 day at room temperature and 5 days at from 0° to 5° C.

Free amino-acids were detected by paper chromatography. Detailed tables are given.

V. R. Jackson.

4392

WATANABE, T. and GOTO, M. Minute constituents of crude drugs. 1. Folic acid in drugs used as

nutrients and tonics. 2. Vitamin B group in Japanese pollens and honeys. 3. On nicotinic acid and vitamin B₁₂ in drugs. *J. Pharm. Soc. Japan*, 1953, **73**, 419-421; 422-425; 841-844. [Res. Lab., Takeda Pharmaceutical Industries, Ltd., Osaka.]

1. The concentration of folic acid in dried spinach, estimated by the growth rate of *Streptococcus faecalis*, was greatest in the root, less in the mesophyll of the leaf and least in the petiole. Of the fresh tissue the mesophyll was richest, and the whole plant above ground was richer than the part below the surface. Folic acid was found also in a few tonic drugs.

2. Pantothenic acid was found in 8 kinds of pollen from various domestic plants, the mean value being 15.3 $\mu\text{g. per g.}$, and in 7 kinds of honey, mean value 1.15 $\mu\text{g. per g.}$ Nicotinic acid was found in pollens, mean value 180 $\mu\text{g. per g.}$, and in honeys, mean value 0.85 $\mu\text{g. per g.}$

3. The nicotinic acid content of extracts of several crude drugs was estimated microbiologically with *Lactobacillus arabinosus* as test organism. To test whether the response was in fact due to nicotinic acid, an extract of *Nuphar japonicum* was treated chromatographically and a growth of micro-organism was found in the fraction having the same R_F value as pure nicotinic acid. By the same method the presence of vitamin B₁₂ was proved in *Ligusticum acutilobum*, which may be of significance, since a crude drug from the plant is used for treating anaemia.—K. H. Coward.

VITAMIN B₁ (ANEURIN, THIAMINE)

4393

SOCIETY FOR ANALYTICAL CHEMISTRY, ANALYTICAL METHODS COMMITTEE. The microbiological determination of thiamine. *Analyst*, 1954, **79**, 118-121.

A report is submitted to the Society for Analytical Chemistry by its Sub-Committee on Vitamin Estimations. The two microbiological methods recommended were the plate-cup method of Jones and Morris (Abst. 3357, Vol. 19) and the tube method of Fitzgerald and Hughes (Abst. 3356, Vol. 19), both with *Lactobacillus fermenti*. Eight laboratories estimated vitamin B₁ by both methods in samples of national flour, wheat germ, dried yeast and vitamin tablets; from the results recommendations are made on the use of the methods and their limitations. It is concluded that an accuracy of ± 12.5 per cent. could be obtained by an analyst experienced in microbiological technique.

SILIPRANDI, D. and SILIPRANDI, N. Separation and quantitative determination of thiamine and

thiamine phosphoric esters and their preparation in pure form. *Biochem. biophys. Acta*, 1954, **14**, 52-61. [Inst. Biochem., Univ. Upsala.] French and German summaries.

A mixture of vitamin B₁ and its mono-, di- and triphosphoric esters was prepared by the method of Viscontini *et al.* (Abst. 3397, Vol. 21). Good separation of small amounts was obtained by ascending paper chromatography. Larger amounts were separated by chromatography on a starch column, with final separation on an ion-exchange resin.

Complete separation with no breakdown of esters was obtained by electrophoresis on paper with acetate buffer. Satisfactory separation was obtained by electrophoresis on starch or cellulose powder columns; with starch part of the separation was brought about by adsorption and not by electrophoresis. Mould growth was prevented by toluene.

Paper chromatography and electrophoresis could be used for separating amounts of from 10 to 100 $\mu\text{g.}$ mixture, but only the latter for amounts up to 2 mg.

Pure di- and triphosphates of vitamin B₁ were prepared and in the pH range from 2 to 6 were stable after 5 days at room temperature. The enzymic activity as cocarboxylase when coupled with yeast apocarboxylase was tested manometrically, and was greater than that of a commercial product.—V. R. Jackson.

WATANABE, A., FUGIWARA, H. and YOSHIDA, T. [Sources of variation in determination of vitamin B₁. 1. Fluorimetric method. 2. Formalin-azo method. 3. Comparison of the errors in vitamin B₁ assay.] *J. Pharm. Soc. Japan*, 1953, **73**, 1272-1277; 1278-1281; 1281-1283. [Res. Lab., Takeda Pharmaceutical Industries, Ltd., Osaka.] English summary.

1. No exact information or conclusion is given. "Procedures and errors in this determination method were theoretically made clear."

2. The formalin-azo method gave an error of only ± 1.7 per cent. and had the advantage that it needed no strict control of the reagents used.

3. "The order in which the less error occurred were ultraviolet absorption measurements, formaldehyde-azo, cyanogen-bromide and ferri-cyanide methods."—K. H. Coward.

DE LANGE, P. and VAN DER MIJLL DEKKER, L. P. A browning reaction between thiamine and glucose. *Nature*, 1954, **173**, 1040-1041. [Central Inst. Nutrit. Res. T.N.O., Utrecht.]

A mixture of equal parts of glucose and vitamin B₁, with a moisture content of 1.5 per cent., was placed in amounts of 0.025 g. in 10 sealed tubes. The tubes were kept at 85° C., one being removed each day and stored at room temperature until all had been treated. There was considerable browning of the mixture during heating. With prolonged heating the amount of both components decreased significantly; colour and fluorescence increased. A solution of the mixture did not brown when heated for 10 days at 85° C.; the reaction occurred only at a low moisture content. A similar test in which arabinose replaced glucose gave greater browning, showing that the rate of reaction was affected by the aldose present; both components were destroyed more rapidly but the degree of fluorescence was about the same.

Spectrophotometric examination of the glucose and vitamin mixture showed that absorption due to glucose was completely suppressed; that of

vitamin B₁ remained unchanged even after 10 days' heat treatment. The adsorption curve showed formation of hydroxymethylfurfural as a result of glucose breakdown.

It is considered that the reaction may contribute to the non-enzymic browning of processed foods and may explain part of the loss of vitamin B₁ in foods treated by heat.—V. R. Jackson.

WAIBEL, P. E., BIRD, H. R. and BAUMANN, C. A. Effects of salts on the instability of thiamine in purified chick diets. *J. Nutrition*, 1954, **52**, 273-283. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

A basal diet for chicks was prepared from purified materials including synthetic vitamins and 6 per cent. of the salt mixture of Briggs *et al.* (Abst. 1140, Vol. 13). For some, glycerol replaced equivalent amounts of sucrose. Vitamin B₁ was incorporated as its chloride hydrochloride or its mononitrate. The diet was stored at known humidities and moisture contents. Vitamin B₁ was estimated by the thiochrome method immediately after the diet was mixed and at intervals afterwards.

When the salt mixture was omitted from the diet, recovery of vitamin B₁ was complete. Its presence caused instability of vitamin B₁ chloride hydrochloride, which was increased by fine milling of the salts. The most destructive components of the mixture were K₂HPO₄ and CaCO₃, and the vitamin was relatively stable if they were replaced by Ca₃(PO₄)₂ and KCl. After 1 week's storage, diets containing 8 per cent. of the unmodified and modified mixtures, respectively, retained 27 and 94 per cent. of the original vitamin B₁. Growth of chicks with the modified mixture was not, however, so satisfactory. MnSO₄ had a destructive effect, which was somewhat delayed.

Vitamin B₁ mononitrate appeared somewhat more stable than the chloride hydrochloride in diets with the unmodified salt mixture, but the composition of the salt mixture was of greater importance. Glycerol was effective as a stabiliser for both forms of the vitamin. The chemical results were confirmed by growth tests with chicks.

The destruction of both forms was retarded by moisture and the addition of 1 per cent. glycerol gave more protection in a dry than in a moist atmosphere. Ascorbic acid appeared to have a slight protective effect in dry diets, but promoted destruction in moist diets.—V. R. Jackson.

WORDEN, A. N., WATERHOUSE, C. E. and PARTINGTON, H. **The utilisation and excretion of vitamin B₁ by the dog.** *Vet. Rec.*, 1954, **66**, 169-174. [Cromwell House, Huntingdon.]

Three dogs of different breed, sex and body-weight were maintained on a standard diet of rabbit, wholemeal bread and milk, with a known intake of water and vitamin B₁. Urine was collected for consecutive 24-hr. periods and vitamin B₁ was estimated. The food intake was the same for an active 19-lb. dog and a lethargic dog of 54 lb.; excretion of vitamin B₁ was not proportional to their bodyweight. The more active dog normally used about twice the amount of vitamin per unit of bodyweight, but when its activity was reduced, the amount excreted was similar to that of the other dog. When the water intake was increased the concentration of vitamin B₁ in the urine decreased and the total daily output remained the same. When the water intake was maintained at the higher level and the environmental temperature was raised by 30° F., the urine volume dropped to one-third, the concentration of vitamin B₁ increased, and the daily loss of the vitamin was significantly reduced.

In the third dog of intermediate weight with a lower food intake, the concentration of vitamin B₁ in the urine remained nearly constant, so that the daily output fluctuated with the urine volume. At the higher temperature loss of vitamin B₁ was just over half that at the lower temperature.

CONRAD, H. R. and HIBBS, J. W. **A high roughage system for raising calves based on early rumen development. 4. Synthesis of thiamine and riboflavin in the rumen as influenced by the ratio of hay to grain fed and initiation of dry feed consumption.** *J. Dairy Sci.*, 1954, **37**, 512-522. [Dept. Dairy Sci., Ohio Agric. Exp. Stat., Wooster.]

Riboflavin was estimated microbiologically and vitamin B₁ by the thiochrome method in rumen samples collected three times daily and in urine collected over 24 hr. from young dairy calves receiving diets with differing proportions of hay and grain and with different types of hay. Cud inoculations into the rumen to establish adult rumen flora early were given weekly for 6 weeks.

Strained rumen liquor contained 4 to 8 times as much vitamin B₁ and riboflavin as an equal weight of diet, indicating microbial synthesis. When alfalfa or clover and timothy hay was given the different ratios of hay to grain had no effect on the synthesis of vitamin B₁ or riboflavin. Urinary excretion was the same in each group. An abrupt change from high-grain to high-roughage diets caused loss of weight for 2 to 4 weeks and synthesis

of vitamin B₁ decreased steeply; calves receiving high-roughage diets from birth had optimum synthesis of vitamin B₁.

In a further test calves received mature timothy hay alone or with a grain concentrate in amounts up to as much as the calves would consume. Vitamin B₁ was synthesised at the highest rate when the ratio of hay to grain was 4:1 and decreased significantly for other ratios. Riboflavin synthesis increased with increased grain up to a ratio of hay to grain of 2:1. A marked increase in the vitamin B₁ and riboflavin content of rumen liquor occurred when dry feed containing clover and timothy hay was given to calves that had received no dry feed up to 13 days. This suggested that the dry feed was a major stimulant in vitamin synthesis. Microscopic examination of different rumen samples by the method of Pounden and Hibbs (Abst. 624, Vol. 19) showed that the number of organisms was higher when the ratio of hay to grain was 4:1. When the ratio was 2:3 several organisms present in mature cattle were absent.

It was concluded that the synthesis of vitamin B₁ and riboflavin in the rumen was favoured by a feed containing a high content of roughage which, among other factors, promoted the growth of desirable micro-organisms.—V. R. Jackson.

CASTER, W. O., MICKELSEN, O. and KEYS, A. **The determination of pyramin.** *J. Lab. Clin. Med.*, 1954, **43**, 469-474. [Lab. Physiol. Hyg., Univ. Minnesota, Minneapolis.]

Measurement of the amount excreted in the urine of the pyrimidine metabolite, pyramin, which occurs from the breakdown of vitamin B₁, was found to be a useful index of vitamin B₁ metabolism (Abst. 2481, Vol. 17); an accurate method of estimating it was, therefore, desirable. A fermentation method was evolved, with Fleischmann's baker's yeast in a fermentometer having specially constructed gas burettes. With 2-methyl-4-amino-5-ethoxymethylpyrimidine hydrochloride, a standard curve was constructed from which pyramin values could be calculated. It was possible to obtain reproducible results with fairly low intakes of vitamin B₁. In rats given autoclaved mixtures, the presence of heat degradation products of vitamin B₁ in the diet interfered with the measurement of pyramin excretion. Such products are, however, considered unlikely to occur in considerable amount in human diets.

ERSHOFF, B. H., GEIGER, E., BITTNER, E. and GRAHAM, T. **Comparative effects of glucose, fructose and sucrose on the thiamine requirement of the rat.** *Exp. Med. Surg.*, 1953, **11**,

N.A. and R., October 1954

293-296. [Emory W. Thurston Labs., Los Angeles, Calif.] French and German summaries.

Weanling rats were given purified diets with or without vitamin B₁ and with glucose, fructose or sucrose as carbohydrate. When vitamin B₁ was present in the diet the rats grew equally well on all three sugars. When the diet lacked vitamin B₁ all the rats gained weight slowly for about 3 weeks and then gradually deteriorated and died. The average survival time ranged from 38 to 46 days but there was no significant difference attributable to the nature of the sugar in the diet.

APTEKAR, S. G. Vliyanie sootnosheniya belkov, zhirov i uglevodov v pishche na razvitie tiaminovogo avitaminoza. [Influence of the proportion of protein, fat and carbohydrate in the diet on the development of vitamin B₁ deficiency.] *Vop. Pitan.*, 1954, **13**, No. 2, 25-30. [Lab. Eksp. Patol., Inst. Pitan., Akad. Med. Nauk SSSR.]

Male rats of from 80 to 90 g. in groups of 12 were fed on diets of starch, casein and lard with salt and vitamin supplements, in which the calories were supplied, per cent., by casein 18, starch 75, and lard 7, or casein 75, starch 18 and lard 7, or casein 18, starch 7 and lard 75. After 2 weeks vitamin B₁ was withdrawn and the clinical condition, weight, pulse rate and urinary pyruvic acid were recorded. Animals having the high-casein and high-starch diets developed signs of vitamin B₁ deficiency equally quickly; the high-fat diet clearly inhibited the development of deficiency.

FRANKEN, J. F. and STAPERT, F. P. Restoration of pyruvate breakdown in pigeon muscle homogenates impaired by thiamine deficiency. *Biochem. biophys. Acta*, 1954, **14**, 293-294. [Lab. Physiol. Chem., Univ. Utrecht.]

Vol. 24, No. 4

The oxidation *in vitro* of pyruvic acid to acetoin with K ferricyanide or molecular oxygen as electron acceptor was impaired in homogenates of breast muscle from pigeons deprived of vitamin B₁. Oxidation by ferricyanide but not by oxygen was restored to normal by addition of vitamin B₁ pyrophosphate. A supernatant fraction obtained by centrifuging a homogenate of normal breast muscle was more effective than vitamin B₁ pyrophosphate, and both together had more effect than either alone.—V. R. Jackson.

4407

SALEM, H. M. Glyoxalase and methylglyoxal in thiamine-deficient rats. *Biochem. J.*, 1954, **57**, 227-230. [Dept. Biochem., Fac. Agric., Univ. Cairo.]

Adult and weanling albino rats received a synthetic diet without vitamin B₁. Signs of severe deficiency appeared after from 3 to 5 weeks. Other groups received a normal diet with vitamin B₁. Methylglyoxal was estimated by the author's modification of Woodward's method (*J. Biol. Chem.*, 1935, **109**, 1).

Methylglyoxal was present in the urine of the deprived but not of the normal rats. On administration of vitamin B₁ to the deprived rats, methylglyoxal disappeared and recovery was complete within a week.

In extracts from the livers of deprived rats, glyoxalase activity on substrates of methylglyoxal or phenylglyoxal was very low; normal activity was regained after administration of vitamin B₁.

Suspensions of the livers from deprived rats, or from normal rats in which glyoxalase was inhibited by kidney antiglyoxalase, produced methylglyoxal from a hexose diphosphate substrate. Methylglyoxal was not produced by the livers of normal animals or of those which had recovered from vitamin B₁ deficiency.

It is concluded that methylglyoxal does not accumulate in the liver of the normal rat because glyoxalase converts it to lactic acid.

DE CARO, L., RINDI, G. and GRANA, E. Metabolic effects of neopyrithiamine and the aneurin contents in the tissues of the rat. *Experientia*, 1954, **10**, 140-141. [Inst. Human Physiol., Univ. Pavia.] Italian summary.

Earlier work (Abst. 1572, Vol. 23) showed that blood pyruvate rose, and the R.Q. and energy expenditure fell, by similar proportions in rats receiving neopyrithiamine or a diet deficient in vitamin B₁. Isolated diaphragm muscle from rats receiving the antivitamin had little glycogen and the onset of fatigue was rapid.

After oral administration of glucose, the R.Q. and metabolic rate rose in the rats on the deficient

diet but not in those given the antivitamin. Comparison of tissues showed that neopyrithiamine reduced vitamin B₁ in muscle, liver and brain to concentrations corresponding with deficiencies of from 5 to 10, 10 and 23 days' duration, respectively. The failure to utilise carbohydrates appeared to be related to the low vitamin B₁ content of nerve tissue.—V. R. Jackson.

EICH, S. and CERECEDO, L. R. **Studies on thiamine analogues. 3. Effects on enzyme systems.** *J. Biol. Chem.*, 1954, **207**, 295-303. [Dept. Biochem., Fordham Univ., New York.]

With a preparation of α -carboxylase obtained from wheat germ by the method of Singer and Pensky (*J. Biol. Chem.*, 1952, **196**, 375), and with vitamin B₁ phosphorylase prepared from rat liver, the effects were studied of some vitamin B₁ analogues on pyruvate decarboxylation, acetyl-methylcarbinol formation and vitamin B₁ phosphorylation. Manometric methods were used to measure decarboxylation and phosphorylation, and photocolormetry for formation of acetylmethylcarbinol. Oxythiamine diphosphate inhibited carboxylase activity, but the extent of the inhibition depended on the order in which the reactants were added to the enzyme. Oxythiamine and neopyrithiamine had no effect on decarboxylation of pyruvate, and oxythiamine had no effect on formation of acetylmethylcarbinol. Neopyrithiamine very strongly inhibited vitamin B₁ phosphorylase, but oxythiamine had no effect. The nature of the inhibitory effects of vitamin B₁ analogues is discussed with consideration of the possible part played by phosphorylation of the analogues.—A. M. Copping.

FUJIIWARA, M. and MATUI, K. **Anti-thiamine factors of the fern.** *J. Biochem., Tokyo*, 1953,

40, 427-434. [Dept. Hyg., Fac. Med., Univ. Kyoto.]

Bracken fern, *Pteridium aquilinum*, is eaten by human beings in Japan.

An aqueous extract of fern was incubated with vitamin B₁ for 30° C. at pH from 3 to 9. At pH 8 destruction of the vitamin was complete, and at pH 6 almost complete. After the extract had been boiled for 30 min. inactivation of vitamin B₁ was complete at pH 8 but did not occur at pH 6. When incubation was in an atmosphere of N₂, there was some degree of inactivation with raw and boiled extract, but it was less than in air. The fraction active at pH 6 did not pass through a cellophane membrane in distilled water but the fraction active at pH 8 did. Presence of pyridine accelerated inactivation by the fraction active at pH 6 but had no effect on that active at pH 8.

VAN DER MIJLL DEKKER, L. P. and DE MIRANDA, H. **The vitamin B₁ content of Dutch wheat and the factors which determine this content.** *Netherlands J. Agric. Sci.*, 1954, **2**, 27-31. [Central Inst. Nutrit. Res. T.N.O., Utrecht.]

Vitamin B₁ was estimated colorimetrically by the method of van der Mijll Dekker (*Chem. Weekblad*, 1947, **43**, 532) in 10 Dutch winter and summer wheats grown for 3 years, 1946-48, on sea clay, sandy sea silt, river clay and sand.

Summer wheats varied widely, Van Hoek was high and Koga low. Summer wheat grown on sea clay or sandy sea silt had more than the same varieties grown on river clay or sand. All varieties were richer in 1947 with a warmer, drier summer than in 1946 or 1948. High content tended to be associated with late seeding date.

Among winter wheats, Alba had significantly more than Carstens V. Clay soils gave higher values than sandy soils. Weather conditions affected the vitamin B₁ content, but not as much as for summer wheat and not on silt soils. Seeding date had no influence.—V. R. Jackson.

RIBOFLAVIN

4144

FARRER, K. T. H. and MACEWAN, J. L. **The thermal destruction of riboflavin.** *Austral. J. Biol. Sci.*, 1954, **7**, 73-84. [Res. Labs., Kraft Foods, Ltd., Melbourne.]

Riboflavin solutions containing 5 μ g. per ml. in

several buffers were made up with pH values from 0.5 to 12.

In recovery tests the range of pH values for complete stability at 120° C. was from 2.0 to 5.0; at pH 8 destruction was complete. At lower temperatures the range was from 1.7 to 5.5 to 100° C., and from

N.A. and R., October 1954

1.3 to 6.5 at 80°C. The tests at very low pH values showed that loss of riboflavin was due to reversible reduction, not to hydrolysis, and that by aeration before or after heating almost complete recovery was obtained.

The thermal destruction of riboflavin at the higher pH values was a first order kinetic reaction. Above the neutral point the rate of destruction was greatly affected by the buffer anions. The Arrhenius equation relating the constant of the rate of destruction to the temperature was followed closely. The rate was affected also by the concentration of riboflavin, and tests with solutions containing 5, 50 and 500 µg. per ml. showed that the equation relating the constant to logarithm of concentration was linear.

The degradation products of riboflavin were shown by chromatography to be ammonia, urea, 1:2-dihydro-6:7-dimethyl-2-keto-1-D-ribityl-3-quinoxalinecarboxylic acid, and an unidentified compound which gave a weak mauve fluorescence in ultraviolet light. A lumichrome with bluish white fluorescence appeared at the beginning of hydrolysis.—V. R. Jackson.

4415

PATTON, S. **The mechanism of sunlight flavor formation in milk with special reference to methionine and riboflavin.** *J. Dairy Sci.*, 1954, **37**, 446-452. [Dept. Dairy Husb., Pennsylvania Agric. Exp. Stat., State College.]

Samples of freshly pasteurised, skimmed milk in flint glass bottles were exposed for 1 hr. to sunlight. Comparable samples were kept in the dark. The strength and type of sunlight flavour were judged by observers familiar with it. When methional (β-methylmercaptopropionaldehyde) was added to skimmed milk in amounts ranging from 0.05 to 2.0 p.p.m., sunlight flavour was reproduced strongly with 0.2 p.p.m., and detectably with 0.05. Other compounds closely related to methional were tested and produced similar flavours but not typical sunlight flavour. The recovery and identification of methional from milk was not attempted, but the formation of methional was demonstrated when 100 mg. riboflavin and 3.0 g. methionine in solution in a quart bottle were exposed to sunlight for 3 hr. From an ether extract of the solution after saturation with NaCl, a 2:4-dinitrophenylhydrazone was prepared with an infrared absorption spectrum identical with that of a similar derivative prepared from pure methional.

Sunlight flavour was not formed with amino-acids other than methionine. In the presence but not in the absence of riboflavin, casein and whey proteins gave sunlight flavour and, of the whey proteins, pseudoglobulin appeared to be most

potent. Casein is, however, considered to be the more important source, since it is in greater concentration, has a higher content of methionine and is the principal component limiting transmission of light.

Results of other investigators and the role of riboflavin and other compounds in photolysis of methionine are discussed.—V. R. Jackson.

4416

GIRI, K. V. and KRISHNASWAMY, P. R. **Studies on the synthesis of riboflavin by a mutant yeast, *Saccharomyces cerevisiae*.** *J. Bacteriol.*, 1954, **67**, 309-313. [Dept. Biochem., Indian Inst. Sci., Bangalore.]

From a bottom strain of brewer's yeast, a mutant top strain of *Saccharomyces cerevisiae* was obtained which was capable of excreting large amounts of riboflavin. The yeast was maintained on wort agar slopes, and transferred to a basal medium on which its requirements for producing riboflavin were studied.

Shaking reduced the yield and, for an adequate supply of air, a large surface was needed on which the culture grew in a thin layer.

Presence of adenine, guanine, xanthine, hypoxanthine, thymine or uracil increased the production of riboflavin, but did not increase growth; all the substances had an optimum concentration above which they had no further effect. Adenine had the greatest effect, thymine and uracil the least. Uric acid inhibited riboflavin production.

Presence of tryptophan, phenylalanine or serine inhibited growth and riboflavin production. Methionine, glycine and arginine increased both, the two first having a greater effect on production of the vitamin.—V. R. Jackson.

KAUNITZ, H., WIESINGER, H., BLODI, F. C., JOHNSON, R. E. and SLANETZ, C. A. **Relation of protein and fat intake to growth and corneal vascularization in galactoflavin-produced ariboflavinosis.** *J. Nutrition*, 1954, **52**, 467-482. [Dept. Pathol., Inst. Ophthalmol., Coll. Phys. Surg., Columbia Univ., N.Y.]

Weanling rats received purified basal diets of varying casein and fat content with or without riboflavin and with or without galactoflavin. Growth and food consumption were recorded and the eyes were examined by slit lamp after dilatation of the pupils with homatropine.

With high riboflavin and 20 per cent. lard, growth rate rose roughly with the protein content of the diet up to 30 per cent. protein. With 18 per cent. protein, growth was about the same as with 74 per cent. Five per cent. protein caused loss of weight at first, then a slow gain. Daily energy intake ranged from 28 Cal. with 5 per cent. protein to 50 Cal. with from 18 to 30 per cent. protein, and 40 Cal. with 74 per cent. protein.

With riboflavin omitted, the food consumption of those with 18 to 30 per cent. casein was two-thirds, and growth half or less, of that of those with the vitamin. Omission of riboflavin had no effect on growth or food consumption with 5 per cent. protein; with 74 per cent. protein and no riboflavin, food consumption was the same as, and growth better than, with 18 per cent. protein.

Rats receiving no riboflavin and given galactoflavin rapidly developed signs of deficiency and lost weight with all levels of protein; the daily energy intake was only 15 Cal. and survival time about 30 days. Those with 74 per cent. protein were most severely affected. With riboflavin and galactoflavin together no toxic effect was seen. It is concluded that a high intake of protein may have toxic effects in riboflavin deficiency.

The signs of deficiency were more severe on diets with 20 per cent. fat than with none or 10 per cent., suggesting that utilisation of protein in riboflavin deficiency was better in the absence of fat.

Corneal vascularisation was found in all rats with 5 per cent. casein and 20 per cent. fat. More protein and riboflavin prevented the eye changes. Fat-free diets delayed their appearance. Similar observations were made on rats receiving galactoflavin. Signs of deficiency were more severe when oxidised replaced fresh lard.—V. R. Jackson.

4421

MAW, A. J. G. **Inherited riboflavin deficiency in chicken eggs.** *Poultry Sci.*, 1954, **33**, 216-217. [Dept. Poultry Husb., Pennsylvania State Univ., State Coll.]

Eggs from 3 related Single Comb White Leghorn hens failed to hatch owing to death of the embryos

during incubation. The white of the eggs lacked the normal greenish-yellow colour which, coupled with the time of death and the appearance of the embryos, suggested that deficiency of riboflavin was involved. The conclusion was confirmed by analysis of the eggs. Injection of riboflavin into the eggs improved hatching, but increase in the riboflavin intake of the hens was without effect. An F_2 population of over 200 birds was reared from the 3 original hens. When the eggs from the F_2 birds were injected with 200 μ g. riboflavin before or up to the 12th day of incubation, the chicks hatched, but all embryos from non-injected eggs died. Of the 88 F_2 females reared, 67 laid normal eggs and 21 laid eggs lacking in riboflavin. It is considered that a recessive gene is responsible, and that birds homozygous for that gene are unable to lay eggs with sufficient riboflavin to ensure the viability of the embryo.

E. M. Cruickshank.

4422

MILLER, E. R., JOHNSTON, R. L., HOEFER, J. A. and LUECKE, R. W. **The riboflavin requirement of the baby pig.** *J. Nutrition*, 1954, **52**, 405-413. [Michigan State Coll., East Lansing.]

Nineteen pigs from 2 litters were taken from the sow after 72 hr. and received a diet of synthetic milk devoid of riboflavin for 4 days; they were then divided into groups receiving no supplement or 1, 2, 3 or 4 mg. riboflavin per kg. solids of the diet. Food was limited only when scouring appeared, mostly during the first week.

All pigs on the basal diet with or without 1 mg. riboflavin showed gross external signs of riboflavin deficiency with a higher incidence of diarrhoea than the others; appetite gradually failed and a state [described as] of multiple deficiencies resulted. Appetite was restored and growth rate improved when a mixture of B vitamins without riboflavin was injected. The livers and kidneys of pigs from these 2 groups showed fatty infiltration; there was much fluid in the peritoneal cavity and pericardial sac, with congestion of the intestine, caecum and colon and some oedema and mucoid degeneration. There were haemorrhages in the rectum. Eye lesions were confined to the lens, cornea and eyelids; there was no corneal vascularisation. The skin showed varying degrees of atrophy and hyperkeratosis. No degeneration of the myelin sheath was found, and no blood change that could be related to the intake of riboflavin.

Pigs receiving 2, 3 or 4 mg. riboflavin per kg. solids of the diet showed no gross sign of deficiency but those receiving 2 mg. gained weight less rapidly and made less efficient use of their food. The requirement for optimum growth and efficiency of feed utilisation was about 3 mg. per kg. solids, which is above the estimate of Forbes and Haines

(Abst. 331, Vol. 23) whose tests were made at a higher environmental temperature; other variables such as relative humidity, genetic make-up and amount of food may have affected the results.

ETREMOV, V. V., MAKARYCHEV, A. I. and TIKHOMIROVA, A. N. **Vliyanie PP-avitaminoza na uslovnorefleksionnyy deyatel'nost' sobak. [Influence of vitamin PP deficiency on conditioned reflexes in the dog.]** *Vop. Pitan.*, 1954, 13, No. 3, 10-15. [Inst. Pitan., Akad. Med. Nauk SSSR, Moscow.]

Two dogs were given a diet containing, per cent., casein 9, maize flour 80, lard 7, and salts 4, and the usual vitamins except nicotinic acid. The casein was freed from tryptophan by acid hydrolysis. Weight was recorded, and urinary N-methylnicotinamide and blood diphosphopyridine nucleotide were estimated. Alterations in cortical activity were demonstrated, and depended on the type of higher nervous activity obtaining in the animal. It is suggested that such alterations in cortical dynamics might be used in the diagnosis of clinical and subclinical nicotinic acid deficiency.

FREY, K. J., SHEKLETON, M. C., HALL, H. H. and BENNE, E. J. **Inheritance of niacin, riboflavin and protein in two oat crosses.** *Agronom. J.*, 1954, 46, 137-139. [Iowa State Coll., Ames.]

F₂ selections from 2 crosses of oats were examined for segregation of nicotinic acid, riboflavin and protein contents. Transgressive segregation for nicotinic acid was present in both crosses, and for high but not low riboflavin. Most of the F₂ selections had a higher riboflavin value than the mean of the 2 parents. Low protein and low nicotinic acid content were dominant in one of the

crosses and each was controlled apparently by a large number of genes.

Heritability varied among crosses but average values were 50, 49 and 15 per cent. for nicotinic acid, riboflavin and protein, respectively.

It is concluded from the heritability values that the development of strains of oats with a higher inherent nicotinic acid or riboflavin content should be easily attained.—V. R. Jackson.

WERTMAN, K., SMITH, L. W. and O'LEARY, W. M. **The effects of vitamin deficiencies on some physiological factors of importance in resistance to infection. 1. Niacin-tryptophane deficiency.** *J. Immunol.*, 1954, 72, 196-202. [Div. Bacteriol., Dept. Biol. Sci., Univ. Pittsburgh, Pa.]

Male albino rats were fed up to a bodyweight of from 40 to 45 g. on a basal diet containing, per cent., sucrose 44.6, purified casein 9, maize grits 40, maize oil 2, salts 4, small amounts of choline chloride, L-cystine, *D*-inositol, *p*-aminobenzoic acid, *d*- α -tocopheryl acetate and 2-methyl-1:4-naphthaquinone, with adequate supplements of vitamins A, D and all members of the B complex. Group 1 of 10 rats was fed to appetite on the complete diet; for group 2 of 12 rats the food intake was reduced to equal that eaten by group 3 of 40 rats, from whose diet nicotinic acid was removed. The average weight gain of the 3 groups in 8 weeks was 216, 41 and 34 g., respectively. On the day before the rats were killed, blood was obtained by tail bleeding. There was no significant difference between the groups in red and white cell counts, but differential counts of the latter showed a large increase in the proportion of neutrophils (polymorphonuclear cells) in the blood of groups 2 and 3.

After the rats had been bled to death under an anaesthetic, the separated serum showed a much reduced complement activity in group 2 compared with group 1, and there was no detectable activity in the serum of group 3. To investigate leucocyte activity, an inflammatory process was excited on the day before death by intraperitoneal injection of a mixture of 15 per cent. nutrient broth and

85 per cent. Locke's solution. After death the exudate from the peritoneal cavity was centrifuged and the sediment corresponding to groups 2 and 3 contained a much lower concentration of leucocytes than that corresponding to group 1. The concentrated supernatant liquid was tested for presence of "leukotaxine" with Menkin's dye technique by intradermal injection into marked areas of the shaved abdomen of a white rabbit, and by observation of the amount of dye accumulated in the marked areas after trypan blue had been injected into the marginal vein of the rabbit's ear. There was no difference in the results to suggest any alteration in capillary permeability caused by inanition or deprivation of nicotinic acid.

Preparations of bone marrow from the tibia showed lymphopenia in groups 2 and 3 compared with group 1.—H. Chick.

VAN REY, W. Zur Frage eines biologischen Antagonismus zwischen Nicotinsäure und Isonicotinsäurehydrazid. [Biological antagonism between nicotinic acid and isonicotinic acid hydrazide.] *Klin. Wochenschr.*, 1954, **32**, 229-230. [Neurol. Klin., Univ. Würzburg.]

In view of the association of nerve lesions with large doses of isonicotinic acid hydrazide in tuberculous patients, a microbiological study was made with *Lactobacillus arabinosus* to find whether the hydrazide was antagonistic to nicotinic acid. With a medium containing adequate nicotinic acid addition of 10 to 100 μ g. isonicotinic acid hydrazide per ml. caused little or no inhibition of growth. With 1000 μ g. per ml. inhibition occurred. The effect on growth of *L. arabinosus* was probably not related to the effect on intermediary metabolism in man.—A. M. Copping.

BUTLER, L. C. and MORGAN, A. F. Leucocyte and thymus changes in the pyridoxine-deficient young and adult male rat. *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 441-444. [Dept. Home Econ., Univ. California, Berkeley.]

Leucocyte counts made on smears of tail blood from young and adult rats given diets lacking in vitamin B₆ showed that there was a decrease in the number of lymphocytes in comparison with rats receiving the vitamin and allowed food to appetite. Other rats paired by weight and given vitamin B₆ showed lymphocyte counts as low as those of deprived rats. Increased numbers of granulocytes were found only in rats deprived of vitamin B₆. Deprivation of vitamin B₆ caused a great decrease in the weight of the thymus gland in young and adult rats within 5 weeks. A smaller decrease occurred in animals given vitamin B₆, with food intake restricted. After deprivation for 8 weeks the weight of the thymus was restored to normal in about 7 weeks when vitamin B₆ was given. The effect of vitamin B₆ deficiency on the output of adrenal hormones (Abst. 3058, Vol. 24)

A diet lacking vitamin B₆ and containing 20 per cent. casein and 20 per cent. maize oil was given to 180 rats with an average initial bodyweight of 142 g., after a week during which 50 μ g. pyridoxine were given daily to each rat. Of 18 groups of 10 rats containing equal numbers of males and females, one group was killed immediately, 8 groups received no pyridoxine, and 9 groups had pyridoxine, of which 4 were fed to appetite and 5 were restricted to the food intake of the deprived animals. One deprived and one non-deprived, restricted or non-restricted, group were killed each week for 8 weeks and in the carcasses moisture, protein and crude fatty acids were estimated. Total vitamin B₆ in the liver and carcass, liver transaminase activity and urea formation by liver slices were estimated.

Rats deprived of vitamin B₆ showed retardation of growth with almost no gain in weight after 4

N.A. and R., October 1954

weeks' deprivation. Skin lesions were not seen until after 6 weeks. The pair-fed, non-deprived rats grew only slightly less well than the fully fed rats and the vitamin B₆ content of the liver and other tissues remained constant; that of the deprived rats decreased within one week. Tissue analyses showed that the difference in bodyweight between the groups was almost entirely due to absence of fat in the deprived rats. No significant difference in the protein content of the body or the N metabolism occurred for at least 4 weeks, by which time total crude fatty acids and total vitamin B₆ values had fallen to steady low levels in the deprived rats. In rats having vitamin B₆ the transaminase activity for aspartic acid and glutamic acid and for alanine and glutamic acid systems increased with age; those in deprived rats changed very little. The probable secondary relation of changes in N metabolism to primary changes in fat metabolism is discussed.

A. M. Copping.

DESKACHAR, H. S. R. and McHENRY, E. W. **Some effects of vitamin B₆ deficiency on fat metabolism in rats.** *Biochem. J.*, 1954, **56**, 544-547. [Dept. Pub. Health Nutr., Univ. Toronto, Canada.]

Rats with an average initial weight from 120 to 130 g. were given fat-free basal diets lacking vitamin B₆, and containing 94 per cent. casein, or 74 per cent. sucrose and 20 per cent. casein. Some rats received 50 µg. pyridoxine hydrochloride daily, some 20 mg. linoleic acid and some both. The composition of the carcass and liver was examined after 8 or 10 weeks of the experimental diets. The total fat in the liver was greater in rats having the high-casein diet than in those having the high-sucrose diet, and deprivation of pyridoxine or addition of linoleic acid had no effect. The total body fat was less in rats having the high-casein diet and, with both diets, lack of pyridoxine decreased it. The decrease was partly prevented by administration of linoleic acid. In rats not given pyridoxine the amount of phospholipins and unsaturated fatty acids was about the same as in rats given the vitamin. The occurrence of fat synthesis in the rats not given pyridoxine was shown by the incorporation into the body fats of glucose labelled with ¹⁴C to the same extent as in rats having pyridoxine. It is suggested that the lower total fat content of deprived rats might have been due to more rapid utilisation rather than to failure of synthesis.—A. M. Copping.

DINNING, J. S., YOUNG, J. M. (Jr.), SIMMONS, M. R. and DAY, P. L. **Effects of a combined deficiency of vitamins E and B₆ on blood picture of rat.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 280-282. [Dept. Biochem., Univ. Arkansas Sch. Med., Little Rock.]

Restriction of weanling Sprague Dawley rats to a diet deficient in vitamins E and B₆ for 105 days caused counts of total leucocytes which were about double those in animals given the vitamins. The increase was most pronounced in the peripheral neutrophils, which reached 10,500 per µl. compared with only from 1500 to 2400 in rats given the vitamins. Administration of vitamin E or vitamin B₆ effectively prevented the increase of leucocytes, but there were differences in the growth rate according to which vitamin was given. The average final weight without any supplement was 102 g., with vitamin E 106 g., with vitamin B₆ 194 g., and with both vitamins 223 g. The rats without vitamin B₆ exhibited slight lymphopenia, which was not affected by vitamin E. None of the animals developed anaemia.—T. Moore.

BIEHL, J. P. and VILTER, R. W. (with BEALL, F. C. and KENNEDY, C. E.) **Effect of isoniazid on vitamin B₆ metabolism; its possible significance in producing isoniazid neuritis.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 389-392. [Dept. Int. Med., Coll. Med., Univ. Cincinnati, Ohio.]

Peripheral neuritis occurred as a side effect in 14 of 36 patients receiving isoniazid (isonicotinic

acid hydrazide) for tuberculosis, but not in 20 others who received pyridoxine in addition to isoniazid. In some patients pyridoxine cured the neuritis if it was given at the onset of symptoms; in others it was ineffective, and late residual neuritis failed to respond in the 22 patients treated. Patients receiving isoniazid excreted in the urine excessively large amounts of vitamin B₆, and an increased amount of xanthurenic acid after a test dose of tryptophan. The evidence of abnormal vitamin B₆ metabolism in patients taking isoniazid might account for the occurrence of peripheral neuritis. No contra-indication to the simultaneous administration of pyridoxine is at present known.—A. M. Copping.

4443

KOTAKE, Y., INADA, T. and MATSUMURA, Y. **Research on xanthurenic acid. 5. Experiments of protracted accumulative effects of xanthurenic acid causing chronic diabetic symptoms in white rats.**

KOTAKE, Y. and INADA, T. **6. Effect of xanthurenic acid upon glycogen amount in liver, heart muscle and skeletal muscle.** *Proc. Japan Acad.*, 1953, **29**, 405-410; 411-414. [Dept. Biochem., Wakayama Med. Coll.]

For earlier work see Abst. 3061, Vol. 24.

5. In order to maintain continuously a concentration of xanthurenic acid in the organism, groups of about 8 young rats were given a diet of, per cent., casein 25, butter 35, salts 2, agar 3, sugar 5, starch 28 and yeast 2. They excreted 1 mg. xanthurenic acid daily in the urine and when, for the first 30 days, they received also 10 mg. tryptophan daily the amount excreted was from 2 to 3 mg. Bodyweight increased steadily and reached a maximum mean weight of 325 g. about the 170th day. The mean blood sugar value increased also. The rats began to lose weight about the 200th day and died about the 240th day.

In another experiment concentration of xanthurenic acid was maintained in the body by deprivation of vitamin B₆ and administration of 10 mg. tryptophan daily. The amount of xanthurenic acid in the urine was from 4 to 7 mg. daily. Blood sugar was raised, and tests showed a much lowered sugar tolerance.

With a diet high in casein and fat, and deficient in vitamin B₆, histological examination of the pancreas showed severe pathological changes in the beta cells of the islets of Langerhans.

The cumulative effect over a long period of xanthurenic acid in causing diabetes in rats is considered to be proved.

6. Rats weighing about 150 g. were fed for a week on a diet of, per cent., casein 22, agar 3, butter 10, starch 53, salts 6, yeast 2 and sugar 5. They were fed for the last time 24 hr. before they were killed; 200 mg. xanthurenic acid per kg. bodyweight were injected intraperitoneally, and the rats were killed 4, from 6 to 8, or 72 or more, hr. later. Blood sugar and liver glycogen were estimated.

Blood sugar was above normal after the first interval of 4 hr., somewhat below normal after the second interval, and again above normal after the third interval; such behaviour of the blood sugar is regarded as characteristic after injection of xanthurenic acid.

The content of glycogen in the liver was below normal in all 3 periods, but was higher in the middle period of low blood sugar than in the preliminary period of high blood sugar, and lowest of all in the third period. In the heart muscle the amount of glycogen rose progressively above normal from the moment of injection of xanthurenic acid. In skeletal muscle it decreased gradually. The results are like those in alloxan diabetes.—E. M. Hume.

4444

KRATZER, F. H., WILLIAMS, D. E., MARSHALL, B. and DAVIS, P. N. **Some properties of the chick growth inhibitor in linseed oil meal.** *J. Nutrition*, 1954, **52**, 555-563. [Dept. Poultry Husb., Univ. California, Davis.]

Diets containing 30 per cent. of different linseed oilmeals depressed the growth of chicks. The growth inhibitor was destroyed by treatment with water or by autoclaving but not by dry heat. It is, therefore, suggested that the inhibitor is destroyed by chemical, and not by enzymic or microbiological action. For counteracting the inhibitor, addition to the diet of 37.5 mg. per kg. of pyridoxine was twice as effective as a daily intramuscular or intraperitoneal injection of 1 or 5 mg. pyridoxine. Pyridoxine, pyridoxal and pyridoxamine were equally effective, on a molar basis. Aureomycin did not improve the growth of chicks given linseed oilmeal, which showed that it did not appreciably stimulate the intestinal synthesis of vitamin B₆.—E. M. Cruickshank.

PANTOTHENIC ACID

4445

TOEPFER, E. W., ZOOK, E. G. and RICHARDSON, L. R. **Microbiological procedure for the assay of pantothenic acid in foods: results compared with those by bioassay.** *J. Assoc. Off. Agric. Chem.*, 1954, **37**, 182-190. [Bur. Human Nutrit., U.S. Dept. Agric., Washington 25, D.C.]

Preliminary experiments with yeast as test material showed that a mixture of intestinal phosphatase and pigeon-liver enzymes gave satisfactory liberation of bound pantothenic acid so that a consistent maximum response was obtained in microbiological estimations with *Lactobacillus arabinosus* 17-5. The optimum amounts of liver phosphatase and Dowex-treated pigeon-liver enzymes for full release of the vitamin were estimated, and the results were compared with those obtained with Mylase-P as the releasing enzyme. The results of the microbiological methods were compared with those of a test with rats. Reasonably good agreement was found in the values for carrots, dried egg, kale, groundnuts, pork liver and brewer's yeast, provided that the samples for the microbiological tests were prepared by digestion with intestinal phosphatase and pigeon-liver enzymes. Other means of extraction gave values significantly lower than those of the rat tests.

BERGAMINI, C. Riconoscimento cromatografico dell'acido pantotenico e separazione di vitamine dell "complesso B". [**Chromatographic identifications of pantothenic acid and separation of vitamins of the B complex.**] *Sperimentale*, 1953, **4**, 38-44. [Ist. Chim. Anal., Univ. Florence.]

The method depended on the acid hydrolysis of pantothenic acid and estimation, from the brown colour with iodine, of the β -alanine formed. The violet colour given with ninhydrin was used in confirmation. The paper chromatogram was of the radial type. The solvent was butanol, acetic acid and water in the proportion 4:1:5. The method could be used quantitatively with a descending chromatogram. Reactions are given also for identification of vitamin B₁, riboflavin, pyridoxine and nicotinamide.—E. M. Hume.

4447

REID, M. E. and BRIGGS, G. M. **Nutritional studies with the guinea pig. 2. Pantothenic acid.** *J. Nutrition*, 1954, **52**, 507-517. [Lab. Biochem., Nat. Inst. Health, U.S. Dept. Health.]

Guineapigs aged from 10 to 21 days were kept in screen-bottomed cages, and given a purified diet

lacking pantothenic acid for 6 weeks. Mortality was high among the guineapigs given the diet from an early age. With a supplement of pantothenic acid good growth was obtained with the same diet. The deprived guineapigs showed poor weight gains, had rough coats, with generally poor condition, and finally developed diarrhoea, lost appetite and died. The adrenal glands showed hyperaemia, enlargement and, in some, haemorrhages. Preliminary blood studies showed no change in Hb, haematocrit, total leucocytes or granulocytes, in moderate states of deficiency.

The pantothenic acid requirement of the guineapig was investigated with groups of animals having 10, 15, 20, 30 or 40 mg. pantothenic acid per kg. diet. Ten mg. was inadequate but 20 mg. was fully sufficient. There was no evidence that inclusion of large amounts of ascorbic acid in the diet improved condition on a suboptimum intake of pantothenic acid.—A. M. Copping.

ZUCKER, T. F. and ZUCKER, L. M. **Pantothenic acid deficiency and loss of natural resistance to a bacterial infection in the rat.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 517-521. [Dept. Pathol., Coll. Phys. Surg., Columbia Univ., New York.]

When young rats were given from 3 weeks of age a purified diet lacking pantothenic acid but otherwise adequately supplemented, unexplained sudden death often occurred within 21 days. A respiratory infection was found to be present which produced a serofibrinous pleural and pericardial exudate with small white abscess-like nodules in the lungs and sometimes also in the liver, kidneys and spleen. The cause of the infection was identified as a corynebacterium hitherto considered pathogenic only for mice. The animals remained in good condition until shortly before death. Weanling rats appeared to be more susceptible to the infection when deprived than rats deprived at 15 weeks of age or when even older.

The problem of such an apparent loss of natural resistance to a specific infection is discussed.

A. M. Copping.

4451

SERONDE, J. (Jr.) **Resistance of rats to inoculation with corynebacterium pathogenic in pantothenic deficiency.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 521-524. [Dept. Pathol., Coll. Phys. Surg., Columbia Univ., New York.]

The observation of Zucker and Zucker (see preceding Abst.) that young rats deprived of pantothenic acid became susceptible to infection with a type of corynebacterium was further investigated with the same strains of rats and the same basal diet with or without addition of pantothenic acid. Inoculation of 0.15 ml. of a broth culture of the organism produced typical infection in rats deprived from 3 weeks of age of pantothenic acid for as little as 16 days, but not in animals given pantothenic acid. The failure of

resistance occurred before any sign of deficiency could be detected. In rats given the deficient diet at 4 weeks of age considerable immunity had been built up and the lesions that occurred after inoculation often were localised and subsequently healed completely.—A. M. Copping.

BIOTIN

4454

DHYSE, F. G. **A practical laboratory preparation of avidin concentrates for biological investigation.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 515-517. [Nat. Cancer Inst., Bethesda, Md.]

Avidin concentrate was prepared by dissolving dried egg white in water brought to pH 5.1 with N HCl. Acetone was added and the precipitate was removed and extracted with 1 per cent. NaCl. The filtrates were dialysed for 2 days at 5° C. against distilled water, and the avidin was precipitated with cold ethanol from the salt solutions. After centrifuging, the precipitate was freeze-dried. For dialysis, cold running tap water low in Fe could be used.

Yeast was grown in the medium of Hertz (Abst. 238, Vol. 13) containing 10^{-4} μ g. biotin per test tube; the avidin concentrate was added in graded amounts and its inhibiting action was estimated. In a typical test, from 800 g. dried egg white containing initially 3200 units avidin activity, a concentrate was obtained containing 1200 units in 800 mg., a recovery of 38 per cent. Of the loss, 1122 units could be accounted for. A unit of avidin activity is defined as "that amount required to completely neutralize the yeast growth supported by one μ g. of free crystalline biotin". The results are similar to those of Eakin *et al.* (Abst. 2102, Vol. 11) with fresh egg white. The concentrate corresponded with the fraction XA of avidin reported by Fraenkel-Conrat (Title 39, Vol. 23).—V. R. Jackson.

4455

TERROINE, T. (with CANNEPIN, M. and BUISSON, F. L.) **Protection importante contre la**

carence en biotine par plusieurs systèmes oxydo-réducteurs. [Protection by several oxidation-reduction systems against biotin deficiency.] *Arch. Sci. physiol.*, 1954, **8**, 61-89. [Lab. Biochim. Nutrit., C.N.R.S., Bellevue, Seine-et-Oise.]

Male albino rats received basal diets containing egg white with or without biotin, and some groups received in addition methylene blue, neutral red or ascorbic acid.

Methylene blue, neutral red and ascorbic acid each delayed the onset of signs of biotin deficiency and reduced the initial number of animals affected. The protection against these signs given by the first 2 substances was only temporary but ascorbic acid often gave permanent protection. Survival time was increased by methylene blue and ascorbic acid but not neutral red. The severity of signs in rats not receiving any of these compounds was lessened by increasing 5-fold the amounts of vitamins B₁ and B₆ and riboflavin in the diet.

Deficient rats had greatly increased protein requirements with ammonia in urine, and administration of oxidation-reduction compounds had no effect. Methylene blue did not prevent loss of weight in deficient rats; neutral red and ascorbic acid allowed growth in some at normal rate. There was no relation between growth rate and degree of severity of signs.

Biotin deficiency caused a secondary deficiency of ascorbic acid if the biotin concentration in liver and adrenals fell below 25 and 10 per cent. of normal, respectively. It appeared that the oxidation-reduction compounds could replace biotin temporarily but it is concluded that there was a distinction between clinical signs, alopecia,

N.A. and R., October 1954

"spectacle" eyes and abnormal gait, which these compounds alleviated, and those which were followed by death.

In discussion, it is concluded that the protection given by methylene blue, neutral red and ascorbic acid, was probably due to their roles as transporters of hydrogen but that biotin itself, though presumably acting in hydrogen transport, must also participate in unidentified reactions governing growth and normal N metabolism.

MOAT, A. G. and LICHSTEIN, H. C. **The role of biotin in carbohydrate metabolism of *Saccharomyces cerevisiae*.** *Arch. Biochem. Biophys.*, 1954, **48**, 300-309. [Dept. Bacteriol., Univ. Minnesota, Minneapolis.]

A strain of *Saccharomyces cerevisiae* was grown in media with graded amounts of biotin. Growth increased with amounts of biotin increasing from 10^{-4} to 10^{-2} μ g. per ml. Stimulation of fermentation and oxidation of glucose by biotin could be demonstrated, but only between certain critical concentrations.

Sucrose and fructose were oxidised by the yeast at the same rate as glucose, and biotin stimulated the oxidation of all 3 sugars to the same degree. There were small differences in the extent to which biotin stimulated fermentation of the 3 sugars.

In absence of biotin, aspartic acid stimulated the rate of O_2 consumption to about half the extent to which it was stimulated by biotin. There was no additive effect with biotin. The effect of aspartic acid on fermentation in absence of biotin was variable; a combination of biotin and aspartic acid was more effective than either alone.

It is suggested that biotin plays a part in carbohydrate metabolism by contributing to the synthesis of an enzyme or enzymes connected with respiration, and by acting as a cofactor in fermentation, possibly in connection with the phosphohexoisomerase reaction.—V. R. Jackson.

UMEZAWA, H., OIKAWA, K., MAEDA, K. and OKAMI, Y. **Anti-biotin activity of thiazolidone antibiotic.** *Jap. J. Med. Sci.*, 1953, **6**, 395-403. [Nat. Inst. Health, Tokyo.]

A new antibiotic obtained from *Streptomyces cinnamomensis* was a thiazolidone derivative. Its inhibitory effect on the growth of *Mycobacterium tuberculosis* was studied by dilution methods and by a cup plate technique. The inhibition was overcome by addition of very low concentrations of biotin and by large amounts of desthiobiotin. Pimelic acid exhibited no antagonistic effect to the antibiotic. The antibiotic was the first known naturally occurring antimetabolite for biotin. It was not toxic for animals and its biological effect appeared to be restricted to metabolic processes requiring biotin.

A strain of *Saccharomyces cerevisiae* producing white colonies in presence of biotin and red colonies in its absence was found useful in demonstrating the antagonistic effects of the antibiotic to biotin.—A. M. Copping.

p-AMINO BENZOIC ACID

RODHAIN, J. **Diète lactée et acide paraminobenzoïque dans l'infection due au *Plasmodium vinckei* chez la souris.** [Milk diet and p-aminobenzoic acid in *Plasmodium vinckei* infection of the mouse.] *Ann. Soc. belg. Méd. trop.*, 1953, **33**, 459-461. [Inst. Méd. Trop. Prince Léopold.] French and Flemish summaries.

Hawking (Abst. 4301, Vol. 23) reported that

addition of p-aminobenzoic acid, 1 part per 1000, to milk robbed it of its protective action for mice against *Plasmodium berghei*. With the technique previously used (Abst. 2209, Vol. 24), it is now shown that mice infected with *Pl. vinckei* survived when fed on milk diet and succumbed when p-aminobenzoic acid was added.

BRODY, G. **Effects of pteroylglutamic acid and vitamin B₁₂ deficiencies in chicks infected with *Ascaridia galli*.** *Exp. Parasitol.*, 1954, **3**, 240-250. [Dept. Bacteriol., Michigan State Coll., East Lansing.]

A semi-synthetic diet, complete or lacking vitamin B₁₂ or pteroylglutamic acid or both, was given to day-old chicks. After two weeks on the diet the chicks were infected by mouth with about 500 ascarid eggs. They were killed 3 weeks later. The number of worms and their average length were used as criteria for judging the effects of the dietary supplements. Lack of vitamin B₁₂ and pteroylglutamic acid resulted in a high rate of infestation. With deficiency of pteroylglutamic acid alone, the number of worms was increased; with deficiency of vitamin B₁₂ alone, the length but not the number was increased. When both vitamins were present the number and length of the worms were significantly less. In chicks deprived of both vitamins addition of vitamin C to the diet decreased the number of worms. Leucovorin was able to produce the effect of pteroylglutamic acid and vitamin B₁₂. A diet low in vitamin B₆ caused an increase in the number of worms, and if vitamin B₆ was entirely absent almost all the chicks died within 4 weeks.—A. M. Copping.

DOCTOR, V. M., ELAM, J. F., SPARKS, P., LYMAN, C. M. and COUCH, J. R. **Studies on the conversion of folic acid to citrovorum factor by avian liver homogenate.** *Arch. Biochem. Biophys.*, 1954, **48**, 249-255. [Dept. Biochem., Texas Agric. Exp. Stat., College Station.]

The conversion of folic acid to citrovorum factor was studied *in vitro* in liver preparations from hens which had received a practical poultry ration, or a purified diet, or a diet lacking in vitamin B₁₂. In aerobic conditions addition of folic acid or ascorbic acid increased the production of citrovorum factor measured microbiologically with *Leuconostoc citrovorum* as test organism. Addition of both substances had a much greater effect. When conversion proceeded in an atmosphere of nitrogen the effect of ascorbic acid was less and it did not enhance the effect of added folic acid. When vitamin B₁₂ was added *in vitro* it had little effect but injection of vitamin B₁₂ into the hens throughout the period of preparation increased the ability of the liver to synthesise citrovorum factor, and increased the storage of vitamin B₁₂ and of citrovorum factor in the liver and egg yolk.

KISLIUK, R. L. and SAKAMI, W. **The stimulation of serine biosynthesis in pigeon liver extracts by tetrahydrofolic acid.** *J. Amer. Chem. Soc.*, 1954, **76**, 1456-1457. [Dept. Biochem., Sch. Med., W. Reserve Univ., Cleveland, Ohio.]

The interconversion of glycine and serine was induced by an extract of pigeon liver. The extract could be inactivated by treatment with Dowex-1 (chloride) and dialysis against a phosphate buffer. The activity was restored by addition of tetrahydrofolic acid in a manner which suggested that it might be a co-factor in the biosynthesis of serine. The utilisation of formate for synthesis of serine by pigeon liver extracts thus inactivated was restored by addition of tetrahydrofolic acid, combined with adenosinetriphosphate, diphosphonucleic acid, glucose-6-phosphate and Mn⁺⁺, but not by tetrahydrofolic acid alone. Folic acid could act as a substitute for tetrahydrofolic acid in the system converting formate to serine.—A. M. Copping.

LASCELLES, J., CROSS, M. J. and WOODS, D. D. **The folic acid and serine nutrition of *Leuconostoc mesenteroides* P60 (*Streptococcus equinus* P60).** *J. Gen. Microbiol.*, 1954, **10**, 267-284. [Microbiol. Unit, Dept. Biochem., Univ. Oxford.]

A detailed study was made of the requirement of *Leuconostoc mesenteroides* P60 for serine. If excess of glycine was present in the medium the organism could synthesise serine provided that pyridoxal or folinic acid was present or the atmosphere was enriched with CO₂. Pyridoxal was not essential for natural growth if serine was present, but the requirement for serine was then increased. When glycine replaced serine a higher concentration of *p*-aminobenzoic acid or of folinic acid was needed. Folinic acid (leucovorin) could replace *p*-aminobenzoic acid when serine was provided, and it could replace both *p*-aminobenzoic acid and CO₂ when glycine was present in large amounts. Folic acid had no effect on the growth of the organism. With a basal medium containing purines and amino-acids, thymidine could be

N.A. and R., October 1954

substituted for *p*-aminobenzoic acid only when serine was provided. Sulphonamide inhibited growth competitively when *p*-aminobenzoic acid was the limiting factor for growth, but no inhibition occurred if folinic acid was present. When these special needs were provided for, *L. mesenteroides* P60 could be used for estimating serine in materials with a relatively high concentration of glycine and of substances belonging to the folic acid group.—A. M. Copping.

MAKINO, H. **The physiological relationship between pterines and folic acid.** 1. 2. *Nagoya J. Med. Sci.*, 1953, **16**, 95-100; 101-103. [Dept. Physiol., Sch. Med., Univ. Nagoya.]

1. Suspensions were made by the method of Norris and Majnarich (Abst. 569, Vol. 18) of rabbit bone marrow in a solution containing citrate but no glucose. Cell counts were made before and after incubation for 3 hr. at 37° C. with folic acid, xanthopterin or other substances.

With folic acid at a concentration of 10 μ g. per ml. there was much proliferation of cells, particularly reticulocytes, less at 5 μ g. per ml. and none at 50 μ g. per ml. Xanthopterin, leucopterin and pteric acid too caused proliferation of reticulocytes, slight with 0.5, maximum with 5 and none with 50 μ g. per ml. At equimolar concentrations the pteridines and folic acid had similar effects, showing that haemopoietic action depended on the presence of the pteroyl radical; the conclusion was supported by the inactivity of *p*-aminobenzoylglutamic acid, folic acid from which the pteroyl radical had been eliminated.

2. Rabbit bone marrow suspensions were prepared and to each 2 ml. were added 100 or 10 μ g. folic acid and 100, 10, 1 or 0.1 μ g. aminopterin. Reticulocyte counts were made before and after incubation for 3 hr.

Folic acid prevented the inhibitory effect of aminopterin on cell proliferation when present in concentrations of from 10 to 100 times that of aminopterin. Vitamin B₁₂ in place of folic acid was inactive.—V. R. Jackson.

JACOBSON, W. **The mode of action of folic acid antagonists on cells. The function of the *Leuconostoc citrovorum* factor in cell division and the inactivation of aminopterin.** *J. Physiol.*,

Vol. 24, No. 4

1954, **123**, 603-617; 618-632. [Strangeways Res. Lab., Cambridge.]

Studies were made of smears and sections of bone marrow and of intestinal mucous membrane of mice before and after treatment with aminopterin and A-methopterin. Some human bone marrow samples also were available from patients with acute leukaemia. From observations on patients treated with small doses of antagonists, and mice treated with large or small doses, it was concluded that both antagonists in high doses of 1 mg. aminopterin or 5 mg. methopterin given by subcutaneous injection could prevent the dividing cells from completing mitosis. Arrest occurred in the metaphase and the process could not proceed to the anaphase. In mice injected with aminopterin the mitoses in the glands of Lieberkühn in the small intestine were severely affected within 2 hr. Pathological forms including tightly clumped chromosomes in metaphase were commonly seen. The epithelium of the villi was severely damaged and patches of complete breakdown occurred, with subsequent bacterial invasion leading to fatal diarrhoea and septicæmia.

The findings were further examined *in vitro* with embryonic chick fibroblasts and osteoblasts. The damage to dividing cells was apparent within 15 min. after application of aminopterin in concentrations between 1 in 2000 and 1 in 20,000. Cells were not prevented from commencing to divide but were arrested in the metaphase. The inhibitory effect of aminopterin on tissue cultures was found to wear off within 24 hr. even when the antagonist remained present in the medium. The effects of methopterin were similar. In further experiments the mechanism by which aminopterin acts on mitosis in cultures of chick embryo fibroblasts and osteoblasts was investigated in presence of folic acid and citrovorum factor. No protection was given by folic acid, but citrovorum factor in a wide range of concentrations prevented the arrest at metaphase of cell division. It is suggested that citrovorum factor may be essential for the step from metaphase to anaphase, and that the inhibitory effect of aminopterin is due to its occupying the position of citrovorum factor within the cell. The failure of inhibition at the end of prolonged exposure to aminopterin appeared to be due to its direct conversion by embryonic chick cells into an inactive compound. Leukaemic cells from acute mouse leukaemia were able to inactivate aminopterin in 24 hr., but normal bone marrow cells had no effect on the antagonist. Further problems arising from the observations are discussed.—A. M. Copping.

W. B. **A mechanism of the vitamin-sparing effect of antibiotics.** *J. Nutrition*, 1954, **52**, 627-636. [Dept. Biochem., Univ. Wisconsin.]

Day-old chicks were grouped according to weight and for 4 weeks were given a semi-purified basal diet containing 0, 25, or 500 μ g. folic acid per 100 g.; the diets low in folic acid were supplemented with aureomycin, bacitracin or penicillin. Growth was recorded and at the end of the experiments intestinal bacteria were counted. Coliform bacteria were isolated and tested for their ability to synthesise folic acid. Growth was increased by the antibiotic supplements, and in the contents of the ileum and duodenum, coliform bacteria appeared which were capable of producing increased amounts of extracellular folic acid. At the same time the folic acid content of the liver increased. The probable mechanism is discussed by which antibiotics exercise their sparing action on the vitamin requirement of chicks.—A. M. Copping.

SAUBERLICH, H. E. and SCHAEFER, A. E. **Studies on aminopterin, leucovorin and folacin with the chick.** *Poultry Sci.*, 1954, **33**, 107-111. [Dept. Animal Husb., Agric. Exp. Stat., Alabama Polytech. Inst., Auburn.]

On a basal diet lacking folacin, better growth was given by supplements of folacin than of leucovorin. Aureomycin and penicillin enhanced the growth obtained with suboptimum amounts of those supplements, but with the basal diet alone the antibiotics depressed growth. Aminopterin, 5 mg. per kg. diet, proved toxic to 50 per cent. of the chicks within 21 days. With larger amounts, the degree of toxicity increased, and with smaller amounts growth was depressed, but the chicks survived. Aminopterin was more toxic injected than ingested. Injections of folacin or leucovorin or relatively large dietary supplements of folacin counteracted the toxic effect, but penicillin and aureomycin had no protective action. The slight reduction in concentration of ascorbic acid in the liver caused by ingestion of aminopterin was prevented by injection of folacin or leucovorin.

The mechanism of resistance to inhibition of growth by methopterin and aminopterin was studied by measuring the ability of cells and cell-free extracts of *Streptococcus faecalis* to form citrovorum factor. Cell-free extracts were obtained by sonic disruption of cells suspended in a magnetostriction oscillator of the Raytheon Manufacturing Co.

The enzymic formation of citrovorum factor from folic acid by cell suspensions in anaerobic conditions was favoured by presence in the medium of formate or serine but not of glycine. The amount of citrovorum factor formed was increased with ascorbic acid in the medium, and the effect of ascorbic acid was additive to that of formate and serine. With cell-free extracts, optimum formation of citrovorum factor was obtained only with the further addition of magnesium ions, diphosphopyridine nucleotide and adenosinetriphosphate. Formation of citrovorum factor in intact cells of resistant strains of *S. faecalis* was inhibited only by large amounts of aminopterin or methopterin. In cell-free extracts or in cells of organisms sensitive to the analogues inhibition was obtained with much smaller amounts. It is suggested that resistance to the analogues is produced by decrease in the permeability of the cell, whereby the amount of inhibitor reaching the susceptible enzyme system is reduced.

VITAMIN B₁₂

4477

DUMAZERT, C. and VERMEULEN, M. (with GHI-GLIONE, C. and BOZZI-TICHADOU, M.) Sur le titrage biologique de l'activité antipernicieuse des extraits de foie. [Biological estimation of the anti-pernicious-anaemia activity of liver extracts.] *Arch. Sci. physiol.*, 1954, **8**, 37-49. [Lab. Chim., Fac. Méd. Pharm., Marseilles.]

Adult rats, preferably in their second year, were rendered anaemic by a diet containing adequate amounts of carbohydrate, fat, salts and vitamins other than vitamin B₁₂, folic acid and vitamin C, but only very small amounts of protein. In 35 days they lost weight and developed macrocytic anaemia with high mean corpuscular Hb, and a red cell count which had generally fallen to half its original value. A rise in the red cell count, a fall in the mean corpuscular Hb and the occurrence of a reticulocyte crisis were the criteria used in assessing the haemopoietic activity of any preparation. A rat unit of haemopoietic activity was defined as the minimum dose of a substance that would produce the above reactions; by comparison with a standardised U.S.P. liver preparation one rat unit was found to be equivalent to 1/500th of a U.S.P. unit of liver activity. Given by injection, a muscle extract, the amino-acids contained in a casein hydrolysate, Fe, Cu, and folic acid in large doses had no haemopoietic activity. Vitamin B₁₂ given parenterally in doses of from 0.002 to 0.10 µg. also had no appreciable haemopoietic effect, but a single dose of 1.0 µg. produced a good haematological response and a reticulocyte crisis equivalent to that produced by one rat unit of a liver extract. This unit dose of liver extract which was fully active contained far less vitamin B₁₂ than the equivalent minimum active dose of 1 µg. of the vitamin, which suggested that the liver factor active in this anaemia was not vitamin B₁₂ but something else.—L. Wills.

DAWBARN, M. C. and HINE, D. C. (with REMILTON, E. and BOFINGER, E.) The determination of vitamin B₁₂-activity in the organs and excreta of sheep. 1. Microbiological assay methods. *Austral. J. Exp. Biol. Med. Sci.*, 1954, **32**, 1-22. [Div. Biochem., C.S.I.R.O., Univ. Adelaide.]

Full details are given of the use of growth and lactic acid production by *Lactobacillus leichmannii* 313, and of plate cultures of a mutant of *Bacterium coli*, to estimate vitamin B₁₂ activity in urine, faeces, gut contents and liver of sheep. The test materials were extracted by heating in 0.1 N acetate buffer with added KCN under specific conditions which yielded maximum potency. Crystalline vitamin B₁₂ added to the extracts was recovered satisfactorily. With plate cultures the slopes of the curves of response to doses of the standard and of the test material tended to be divergent. Tube cultures of *L. leichmannii* gave more satisfactory curves of response. The potency of extracts of faeces and gut contents appeared to be greater when estimated by plate culture; that of liver was the same by both methods. The statistical analysis of the data is described in two appendixes.—A. M. Copping.

STAPERT, E. M., FERRER, E. B. and STUBBERFIELD, L. The effect of ascorbic acid and trace elements on vitamin B₁₂ assays. *J. Amer.*

Pharm. Assoc., 1954, **43**, 87-90. [Biol. Control Labs., Upjohn Co., Kalamazoo, Mich.]

In microbiological tests, it was found that Cu in a concentration as small as 0.1 p.p.m. caused appreciable destruction of vitamin B₁₂ when the solution was agitated in a Waring Blender. Cu with ascorbic acid had a greater destructive effect on vitamin B_{12b} than on vitamin B₁₂; both reactions were prevented by the addition of KCN or sodium diethyldithiocarbamate. Molybdate, fluoride and manganous ions also caused destruction of vitamin B₁₂ in solutions containing ascorbic acid, but cobalt, magnesium, iodide, ferrous and zinc ions did not; none of them when tested separately affected the stability of vitamin B₁₂ in solution. Spectrophotometric tests confirmed the destruction caused by ascorbic acid and copper and its prevention by KCN.—K. H. Coward.

BARTILUCCI, A. and FOSS, N. E. **Cyanocobalamin (vitamin B₁₂). A study of the stability of cyanocobalamin in liquid formulations.** *J. Amer. Pharm. Assoc.*, 1954, **43**, 159-162. [Dept. Pharm., Univ. Maryland Sch. Pharm., Baltimore.]

For maintaining stability in a mixture of cyanocobalamin and ascorbic acid the most favourable pH was between 6.0 and 7.0. Tetrasodium ethylenediaminetetra-acetate stabilised cyanocobalamin. Ascorbic acid was most stable in high concentrations of propylene glycol with distilled water, glycerine or Sorbo, or a mixture of glycerine and Sorbo. Cyanocobalamin was doubtfully stable in high concentrations of propyleneglycol and in vehicles containing glucose. For a mixture of cyanocobalamin and ascorbic acid, a vehicle composed of equal parts of propyleneglycol and glycerine afforded maximum stability, about from 80 to 85 per cent. of each being retained after 6 months' storage at 40°C. No cyanocobalamin and only about 10 per cent. of ascorbic acid was lost on storage for 6 months at room temperature. It is suggested that the decomposition products of ascorbic acid play an important part in the decomposition of cyanocobalamin.—K. H. Coward.

Quantitative electrophoretic analysis of the pseudovitamin B₁₂ preparation, in which Holdsworth and co-workers (Abst. 2958, Vol. 23) had demonstrated two microbiologically active components, yielded 90 per cent. pseudovitamin B₁₂, 9 per cent. of a microbiologically active red substance and 1 per cent. of an inactive red substance. The active pigment was similar in composition to pseudovitamin B₁₂ but differed in containing adenine in the nucleotide linkage instead of 5:6-dimethylbenzimidazole. It was termed pseudovitamin B_{12d} and yielded on acid hydrolysis 2-methyladenine, the natural occurrence of which has not previously been reported.—A. M. Copping.

A flock of 50 lambs run on cobalt-deficient pasture showed signs of unthriftiness at the age of 5 months. In 5 groups of 10 they were then given 7 mg. cobalt once a week by mouth, or an injection of 100 µg. vitamin B₁₂ once a week or 1000 µg. once a week by mouth, or a single injection of 1000 µg., or no treatment. Treatment with cobalt or regular injection of 100 µg. vitamin B₁₂ gave a good growth response. An oral dose of 1000 µg. vitamin B₁₂ was not enough. A single injection of 1000 µg. vitamin B₁₂ gave a limited growth response but the lambs began to lose condition 2 weeks after the injection. Although treatment of cobalt deficiency with vitamin B₁₂ was effective it was too costly. The best method of controlling the deficiency under New Zealand conditions is held to be by topdressing pastures with fertilisers containing cobalt.—A. M. Copping.

Preliminary details are given of a protein complex isolated from sow's milk in the process of purification of the proteins, and from desiccated gastric mucosa (Abst. 1840, Vol. 24). The substance was pink, with absorption maxima at 278 and 362 m μ ., corresponding to the protein and cyanocobalamin fractions, respectively. The complex contained 23.6 μ g. cyanocobalamin per mg.; the amount found by Wijmenga *et al.* (Abst. 3089, Vol. 24) was 12.3 μ g. per mg. in a preparation from pig's stomach. The mode of linkage was investigated by adding ¹⁴CN-labelled cyanocobalamin to a partly purified protein preparation from gastric mucosa. Combination occurred after removal from the cobalamin molecule of the nucleotide and the most labile amide group, but not after hydrolysis to hexa- or hepta-acids. The radioactivity was present in the pink protein, showing that the protein did not displace the cyanide during combination with the vitamin. By blocking specific groups in the protein it was established that free —SH groups were not needed but that —NH₂ or >NH groups were probably involved. Microbiological estimation of the vitamin B₁₂ potency of enzymic digests of the complex suggested that they contained peptide conjugates of cyanocobalamin.—A. M. Copping.

- BAUREDEL, W. R., HOERLEIN, A. B., PICKEN, J. C. (Jr.) and UNDERKOFLEER, L. A. Selection of diet from studies of vitamin B₁₂ depletion using unsuckled baby pigs. *J. Agric. Food Chem.*, 1954, **2**, 468-472. [Vet. Med. Res. Inst., Ames, Iowa.]

Baby pigs were caught in sterile bags at birth or removed by caesarean section and were kept isolated in separate cages; they were reared in early experiments on cow's milk supplemented with mineral salts and egg, and in later tests on mixtures of casein and soya bean protein with minerals and vitamins. The mixtures included no antibiotic and no vitamin B₁₂, but some animals received vitamin B₁₂ by intramuscular injection. With cow's milk mixtures scouring did not occur but with synthetic milks it was serious, and was only partly overcome by modifying the diet. With the more satisfactory diets mortality was low during the 8 weeks of the test. Pigs killed at 8 weeks of age showed very low stores of vitamin B₁₂ in the liver, kidneys and pancreas unless the vitamin had been injected. The main difficulty in rearing unsuckled pigs appeared to be their lack of immunity to disease owing to slowness in formation of γ -globulin in the absence of colostrum; electrophoretic analysis of serum from 8 of the pigs showed only about 25 per cent. of the normal amount of γ -globulin.—A. M. Copping.

- CSONKA, F. A., LILLIE, R. J. and MARTIN, W. The maternal diet as a source of growth factors

transmitted by the hen through the egg to the progeny. *J. Nutrition*, 1954, **52**, 285-296. [Bur. Human Nutrit., U.S. Dept. Agric., Washington, D.C.]

Increase in weight of chicks from hens given for 90 days a diet high in protein, as casein, was greater than of chicks from hens on a diet low in protein, from maize. When the breeding diets were supplemented with a vitamin B₁₂ concentrate, the difference in growth of the progeny was not statistically significant. When vitamin B₁₂ was added to the rearing diet the growth response of the chicks was less than when the vitamin was added to the diet of the hens. Dried cow manure added to a rearing diet low in vitamin B₁₂ significantly increased chick growth and was more effective than vitamin B₁₂ alone or combined with cow manure.

In a subsequent experiment the diets of the hens were reversed for a short period. The chicks from hens given the high-protein diet again grew better than those from hens on the low-protein diet. Addition of vitamin B₁₂ to the breeding diets failed to improve the chick's growth. Addition of the vitamin to the rearing mash appreciably increased the growth of chicks from hens on the low-protein diet but increased growth only of the cockerels from hens on the high-protein diet. Addition of cow manure to the rearing mash, after reversal of the maternal diets, produced no significant improvement in chick growth; in some instances growth was actually depressed.

It is suggested that birds on a diet high in casein transmit to their progeny a substance other than vitamin B₁₂ which may be related to the dietary protein.—E. M. Cruickshank.

Blood was analysed from the 18-, 19- and 20-day chick embryos and the newly hatched chicks of hens reared on basal rations deficient in vitamin B₁₂ with or without added vitamin B₁₂. A vitamin B₁₂ supplement given to the hen produced higher total N levels in the embryo blood. N distribution was altered in the blood of embryos from deprived hens, with an increase in N.P.N. and amino-acid N, urea, uric acid and creatinine. It appeared that the presence of vitamin B₁₂ improved the utilisation of N for synthesis of tissue protein, and that lack of the vitamin allowed accumulation of N.P.N. in the blood.

Baby pigs were given a synthetic milk mixture containing alpha-protein and 1.6 per cent. methionine with cerelese, lard, minerals and vitamins except vitamin B₁₂. One group received vitamin B₁₂ and another had dimethylaminoethanol as a methyl acceptor in case lack of vitamin B₁₂ should block its synthesis. The high level of methionine in the diet served as an adequate source of choline even in pigs moribund from lack of vitamin B₁₂. Addition of vitamin B₁₂ to the diet did not affect the amount of choline in the liver or that excreted in the urine. The vitamin B₁₂ content of the liver

N.A. and R., October 1954

was much greater in the pigs receiving the vitamin. No fatty infiltration of the liver or kidney damage was seen in pigs deprived of vitamin B₁₂ but receiving excess methionine. The results of the study suggested that vitamin B₁₂ is not involved in the direct transfer of methyl groups from methionine to choline.—A. M. Copping.

Vol. 24, No. 4

[Lab. Biochem., Nat. Inst. Health, Pub. Health Serv., Bethesda, Md.]

Chicks from hens maintained on a standard ration were given for 4 weeks a diet of soya bean meal, yellow maize, glucose, maize oil, minerals, riboflavin and vitamin D, with or without 0.1 mg. vitamin B₁₂ per kg. Growth on the diet with vitamin B₁₂ was similar to that on a stock diet. When the diet with or without vitamin B₁₂ was modified by substituting 20 per cent. of hydrogenated oil or lard for 20 per cent. of maize, depression of growth occurred, which without vitamin B₁₂ was severe. A similar but less consistent effect was obtained when 20 per cent. of vegetable protein replaced 20 per cent. of maize.

MEITES, J. and FENG, Y. S. L. **Prevention by vitamin B₁₂ of protein catabolic action of cortisone.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 341-344. [Dept. Physiol., Michigan State Coll., East Lansing.]

Five groups of young male rats were given a maize and soya bean diet lacking vitamin B₁₂; after 20 days one continued unchanged, the second received vitamin B₁₂, the third cortisone, the fourth cortisone and vitamin B₁₂, and the fifth the same as the last but with food intake restricted to that of the third group. Urinary N was measured at 10-day intervals. Growth was inhibited by cortisone, but the effect was overcome to some extent by vitamin B₁₂. The increase in the daily loss of N in the urine when cortisone was given was prevented when vitamin B₁₂ was given also but not if the food intake was restricted at the same time. Vitamin B₁₂ had no effect on urinary N in the absence of cortisone. The effect of the vitamin appeared to be related to increase of appetite with increased availability of amino-acids or glucose, and consequent counteraction of the effects of protein breakdown. If large doses of 2 or 4 mg. cortisone were injected, vitamin B₁₂ was much less effective in overcoming weight loss and protein breakdown.—A. M. Copping.

GOMIRATO, G. **Quantitative evaluation of the metabolic variations in the spinal motor root cells, studied by biophysical method and following adequate stimulation (muscular**

fatigue). Action on metabolism of vitamin B₁₂.

J. Neuropathol. Exp. Neurol., 1954, **13**, 359-368. [Neuro-Psychiat. Clin., Univ. Turin.]

Young guineapigs weighing from 250 to 360 g. were run to complete exhaustion on a moving belt and killed 10 min. or 24 or 48 hr. after the end of the exercise. Thin sections of the spinal motor nerve roots taken from the lumbar and cervical spinal enlargements were fixed and photographed in ultraviolet light. Radiographic methods were used to estimate the mass, the protein, and the nucleo-protein of the cells. Some animals were given vitamin B₁₂ by injection before or during the exercise or in the resting stage after exhaustion, and some given vitamin B₁₂ were not exercised. Prolonged muscular fatigue reduced the protein and the nucleo-protein in the motor neurons. Protein values were restored to normal in 24 hr. and nucleo-protein in about 48 hr. Injection of vitamin B₁₂ did not affect the amount of protein or nucleo-protein in resting or fatigued cells, but hastened restoration of nucleo-protein after exhaustion.

RABBI, A., VIVIANI, R. and MARCHETTI, M. Ricerche sul contenuto in vitamina B₁₂ del fegato di ratto tiroxinizzato. [The vitamin B₁₂ content of the liver in rats treated with thyroxine.] *Acta vitaminol.*, 1954, **8**, 85-87. [Ist. Chim. Biol., Univ. Bologna.] French, English, German and Spanish summaries.

Of 18 rats weighing from 80 to 120 g., maintained on the diet of Rando and Causeret (Abst. 3159, Vol. 17), 10 received subcutaneously 1 mg. DL-thyroxine daily. After 10 days all the rats were killed. Those not given thyroxine gained from 40 to 56 g., and those given thyroxine from 12 to 24 g. The vitamin B₁₂ content of the liver, estimated microbiologically with *Lactobacillus leichmanii* 4797 ATCC, in $\mu\text{g.}$ per g. dry tissue, ranged from 277 to 520 for the untreated rats and from 515 to 771 for those given thyroxine.

WANG, H., SCHEID, H. E. and SCHWEIGERT, B. S. Histological studies with rats fed diets containing iodinated casein and different levels of vitamin B₁₂. *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 382-384. [Div. Histol., American Meat Inst. Found., Univ. Chicago.]

Weanling rats were given a diet of maize and soya bean oilmeal with 0.06 per cent. iodinated casein, and with or without 50 $\mu\text{g.}$ vitamin B₁₂ per kg. diet. The animals were killed after 4 or 6 weeks, and their tissues were fixed in Zenker formol and processed by the standard celloidin technique.

No change in the histological picture of the liver, muscle or bone marrow was found in rats deprived of vitamin B₁₂, but in the thyroid gland degenerative changes occurred, which increased as deprivation was prolonged. On administration of vitamin B₁₂ after 4 weeks' deprivation repair of the damage was not complete. Changes occurred also in the testes of deprived rats and they were capable of reversal if vitamin B₁₂ was given after deprivation for 4 weeks. It is suggested that the changes in the thyroid gland and the low spermatogenic activity, shrinkage of seminiferous tubules, and degeneration of interstitial tissue in the testes, might be related to a low output of certain anterior pituitary hormones in animals deprived of vitamin B₁₂.—A. M. Copping.

BROWN, W. O. The use of all-vegetable diets in animal feeding. 2. The growth rate of A.P.F. deficient chicks on supplemented vegetable

N.A. and R., October 1954

protein diets and on animal protein diets.

Res. Exp. Rec. Minist. Agric. N. Ireland, 1952, 47-53. [Minist. Agric. N. Ireland.]

Chicks hatched from eggs of hens maintained on an all-vegetable diet were given diets containing soya bean or groundnut meal with or without supplements of a vitamin B₁₂ concentrate, and growth was recorded for 6 weeks from hatching. With addition of vitamin B₁₂ the mortality was nil, weight increase was much better and utilisation of feed was more efficient. Chicks on standard mash mixtures and those given fish solubles added to the vegetable diet showed greater weight increases than those given vitamin B₁₂ but vitamin B₁₂ was the only supplement capable of preventing death. The growth response to vitamin B₁₂ was not raised to equal that on the stock mash by addition of methionine or of dried rumen contents. The problem of the animal-protein factor requirements of poultry and of the successful practical use of supplements to vegetable diets is discussed.

CARPENTER, K. J., DUCKWORTH, J. and ELLINGER, G. M. **Economies in the use of animal by-products in poultry rations. 2. Vitamin and amino-acid provision for laying hens.** *J. Agric. Sci.*, 1954, **44**, 340-354. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

For part 1 see Abst. 299, Vol. 23.

In birds given all-vegetable rations during the laying period or from hatching to 18 months of age, egg production was equal to that of birds receiving rations containing animal protein. Early growth was somewhat retarded by the absence of animal protein and was accelerated by aureomycin supplements, but neither the final weight of the pullets nor their egg production was thereby affected. The limited amount of fresh droppings available to hens kept on wooden floors which were cleaned daily provided enough of the animal-protein factor to supply their requirements for sustained egg production. When the ration contained 8 per cent. of cereal protein, supplemented with 3 per cent. groundnut meal or white-fish meal, groundnut meal proved significantly inferior to fishmeal; when the amounts were larger the supplements were of equal value. A ration containing 11 per cent. protein, 3 per cent. of which was provided by white-fish meal, proved adequate for good egg production if the birds were kept in laying pens, but appeared to be less adequate for birds kept in straw yards.—E. M. Cruickshank.

4527

JOHNSON, E. L. **Vitamin B₁₂ requirements of hens as affected by choline and penicillin.** *Poultry Sci.*, 1954, **33**, 100-107. [Dept. Poultry Husb., Iowa State Coll., Ames.]

Vol. 24, No. 4

Studies were made during 3 years of the hatching capacity of eggs from hens maintained on a basal all-vegetable ration, with or without a supplement of vitamin B₁₂. On the basal ration alone, hatching capacity was reduced from 80 per cent. to about 48 per cent. in 4 months. In one experiment in which the basal ration contained alfalfa, hatching capacity was not reduced even after 54 weeks, though the growth and viability of the chicks were impaired. When the basal diet was supplemented with 2 µg. vitamin B₁₂ per kg., the hatching capacity of the eggs was good, and the hen's requirement for the vitamin is estimated to be not more than that amount. Supplements of choline or penicillin did not influence the amount of vitamin B₁₂ required for good hatching capacity of the eggs or for viability and growth of the progeny. Rapid growth of chicks with marginal reserves of vitamin B₁₂ was obtained on a vegetable diet supplemented with the vitamin.

E. M. Cruickshank.

4528

HANSEN, M. F., PETRI, L. H. and ACKERT, J. E. **Effects of aureomycin and vitamin B₁₂ used separately as feed supplements on resistance of chickens to *Ascaridia galli* (Schrunk).** *Exp. Parasitol.*, 1954, **3**, 122-127. [Dept. Zool., Kansas State Coll., Manhattan.]

In extension of a previous study (Abst. 504, Vol. 24), a basal all-vegetable diet was given to 512 chicks. Three groups had supplements of vitamin B₁₂ or aureomycin or both. Half the chicks in each group were infected with *Ascaridia galli*. The highest ratio of mortality and infestation were among the chicks on the unsupplemented basal diet. The supplements alone or together prevented death and caused significant reduction of the infestation rate. With vitamin B₁₂ and aureomycin together, growth was improved even in chicks infected with ascarids. The number of parasites was reduced by the supplements. Aureomycin appeared to restrict the growth of the worms, and vitamin B₁₂ promoted it; when both were given, they counteracted one another in their effect on growth.—A. M. Copping.

4529

FERRANDO, R., JOUBERT, L., SALIN, J. and GORET, P. **Sur les répercussions de l'adjonction de quelques antibiotiques à la ration alimentaire du poulet et du porcelet. [Ultimate effects of adding antibiotics to the diet of the chicken and pig.]** *Rec. Méd. vét.*, 1953, **129**, 998-1020.

The effect was studied of adding penicillin, aureomycin, streptomycin or a new antibiotic, soframycin, to a practical ration containing meat and fishmeal supplying ample vitamin B₁₂. The supplements improved weight gain and feed utilisation in pigs and chickens. Some deviation

from normal was observed in the distribution of types of bacteria in the gut flora of both species, but the total bacterial count in the faeces was not appreciably altered. The development of bacteria resistant to antibiotics was investigated, and no change appeared to occur in the pig. In the chicken, however, resistant cocci and *Proteus* sp. were found, and prolonged use of antibiotic supplements in poultry feeding was considered to be possibly dangerous. The pigs and chickens showed no sign of anaphylactic sensitivity to the antibiotics tested.—A. M. Copping.

4530

NORDFELDT, S. Användning av vitamin B₁₂-preparat och antibiotika till svin. [The use of vitamin B₁₂ preparations and antibiotics for pigs.] *Kgl. Lantbrukshögsk. Statens Husdjursförsök Särtryck* No. 103, 1953, pp. 31. English summary.

In the first experiment there were 5 groups each of 8 Landrace weaned pigs, given the following additions to normal cereal meal rations: skimmed milk alone and with bacitracin; extracted rape meal with bacitracin or bacitracin and vitamin B₁₂; soya bean meal, sunflower seed meal, bacitracin and vitamin B₁₂. Chalk, dicalcium phosphate and salt, alfalfa meal and "deltafor" were given also. Bacitracin was an American product with 5 g. of it per lb. given at the rate of 2 lb. supplement per ton meals, and the vitamin B₁₂ supplement contained 3 mg. of the vitamin and 3 g. bacitracin per lb., given at the rate of 5.5 lb. per ton. Bacitracin and vitamin B₁₂, alone or together, had no effect on weight gain to 100 kg. or feed cost. Two further experiments confirmed the results.

In a fourth test 6 groups each of 10 weaned pigs were fed on cereal meals with skimmed milk, or soya bean meal alone or with 10, 15, or 20 g. procaine penicillin per ton meal, or 10 g. penicillin and 10 mg. vitamin B₁₂ per ton meal. Growth with soya bean meal was not good but with 10 g. penicillin, with or without vitamin B₁₂, improved to the level obtained with skimmed milk, and beyond it with the larger amounts of penicillin. In contrast neither penicillin nor an animal-protein factor preparation improved growth, which was poor, with rape meal as source of protein, and with soya bean meal 15 or 20 g. procaine penicillin per ton meal mixed with precipitated chalk had no effect; 15 g. procaine penicillin, in chalk, with 9 mg. vitamin B₁₂ per ton, and 20 g. penicillin mixed with alfalfa meal, gave considerable improvement for a time, but there was no advantage at slaughter weight.

For results quoted here with sows and litters see Abstr. 4371, Vol. 23.

A preliminary experiment in artificial rearing

was made with a single litter of 8 pigs, divided at 10 days of age, so that 4 continued with the sow and 4 were fed on Terralac. At weaning there was no difference between them. From weaning at 8 weeks of age they were fed on an ordinary ration of cereals and skimmed milk without antibiotic. The artificially reared pigs did not do quite as well as the suckled.—I. Leitch.

4531

JORDAN, W. J. The use of a liver extract (vitamin B preparation) in scouring in young piglets. *Vet. Rec.*, 1954, **66**, 215. [Rossett, Nr. Wrexham.]

A solution said to contain liver extract, vitamin B₁₂, vitamin B pyrophosphate and folic acid was used in the treatment of scouring in young piglets. Early cases, 228, were injected subcutaneously with $\frac{1}{2}$ to 1 ml. of this preparation. By the second day their faeces had become darker and firmer and by the third day diarrhoea had ceased. Eight of them required a second dose 5 days later, but in none did the disorder become chronic.

When 90 piglets from herds where scouring had always been prevalent were treated prophylactically with this material at 3 days of age, none developed diarrhoea, but older animals showing debility improved only slightly. [There is no mention of control animals.]—W. A. Greig.

KELLY, R. F., BRAY, R. W. and PHILLIPS, P. H. The influence of vitamin B₁₂ and aureomycin supplementation in the ration on the vitamin B₁₂ activity of pork muscle. *J. Animal Sci.*, 1954, **13**, 332-337. [Dept. Animal Husb., Univ. Wisconsin, Madison.]

In a test with 96 pigs of average initial weight 45 lb., a basal diet was given containing 14, 17 or 20 per cent. protein in a mixture of maize, soya bean meal and alfalfa meal. Groups of 12 pigs having each concentration of protein were given vitamin B₁₂, or aureomycin, or both, or no supplement. When the average weight of the group reached 213 lb. the pigs were killed and vitamin B₁₂ was estimated in the muscle microbiologically with *Lactobacillus leichmannii*. When vitamin B₁₂ was given alone there was an increase of the vitamin in the muscle. With aureomycin alone or combined with vitamin B₁₂ there was no increase and in some groups there was a decrease.

N.A. and R., October 1954

The antagonistic effect of aureomycin on the storage of vitamin B₁₂ in pork muscle was confirmed in a second experiment with 56 pigs; a mixture of B vitamins was given instead of crystalline vitamin B₁₂ and the combination of aureomycin and the vitamin B supplement was then less unsatisfactory than in the first experiment.

Intramuscular fat deposition was found to be inversely related to protein intake, and was unrelated to the supplement of vitamin B complex or aureomycin.—A. M. Copping.

TRIBE, D. E., BOND, J. M. and OSBORNE, A. D. **Response of cobalt-deficient sheep to oral administration of penicillin.** *Nature*, 1954, **173**, 728. [Sch. Vet. Sci., Univ. Bristol.]

Two sheep were maintained on hay and concentrates from a Co-deficient farm, containing, respectively, 0.06 and 0.06 p.p.m. Co and 86 and 122 p.p.m. Fe. After 5 weeks they were given 50,000 units of crystalline sodium penicillin G by mouth daily for 7 weeks. The effect of the penicillin was not apparently felt at first, but after the third week feed intake and rate of weight gain improved. The penicillin contained no Co, but the suggestion is made that it caused a change in the rumen flora which promoted the bacterial

synthesis of vitamin B₁₂ and the better utilisation of the very small amount of Co in the diet.

PETRUSHANOV, V. N. **Sintomitzin-profilakticheskoe snedstvo pri avitaminoznoi dispepsii u telyat. [Synthomycin as a prophylactic in vitamin deficiency dyspepsia in calves.]** *Veterinariya*, 1953, **30**, No. 6, 35. [Sovkhoz "Novoe", Vologodsk. Oblast.]

Dyspepsia and diarrhoea in newborn calves, thought to be due to vitamin deficiency arising from unusually early stallfeeding of the cows, were improved or prevented by the administration of synthomycin in 3 daily doses of from 0.5 to 1 g.—D. W. Taylor.

4537

REGE, D. V. and SREENIVASAN, A. **Influence of folic acid and vitamin B₁₂ on the impairment of nucleic acid synthesis in *Lactobacillus casei* by aureomycin.** *Nature*, 1954, **173**, 728-729. [Foods Sect., Dept. Chem. Technol., Univ. Bombay.]

The synthesis of pentose nucleic acid and deoxy-pentose nucleic acid was studied in cells of *Lactobacillus casei* in media with and without aureomycin and with additions of folic acid or vitamin B₁₂ together or separately. Aureomycin in a concentration of 300 mμg. per 100 ml. inhibited synthesis of both nucleic acids, and the inhibition was overcome by addition of 200 mμg. folic acid or 400 mμg. vitamin B₁₂.—A. M. Copping.

FRAENKEL, G. and PEH-I CHANG. **Manifestations of a vitamin B_T (carnitine) deficiency in the larvae of the meal worm, *Tenebrio molitor* L.** *Physiol. Zool.*, 1954, **27**, 40-56. [Dept. Entomol., Univ. Illinois, Urbana.]

Inclusion of 0.35 μg. carnitine per g. diet allowed the larvae of *Tenebrio molitor* to grow at almost the normal rate on a synthetic mixture of casein, glucose, cholesterol, salt mixture and all known vitamins of the B complex. Larvae having no carnitine died after from 4 to 6 weeks, usually immediately after a moult. Complete recovery of normal growth, colour and condition was observed if carnitine was given after from 3 to 4 weeks' deprivation. The dose of 0.35 μg. carnitine per g. diet did not suffice to produce viable adult pupae, and 1.5 μg. appeared to be needed for optimum growth. The failure of growth in larvae deprived of carnitine was apparently due to cessation of feeding. If normal larvae were starved their fat

content decreased and their water content increased. Larvae deprived of carnitine showed a higher fat content and lower water content than starved, normal larvae. Loss of water was thought to be a contributory cause of death at the moulting stage.—A. M. Copping.

FRÖBRICH, G. **Neue Ergebnisse experimenteller Untersuchungen zur Ernährungsphysiologie des Reismehlkäfers *Tribolium confusum* Duval (Tenebrionidae, Coleoptera). [Physiology of nutrition of the flour beetle *Tribolium confusum*, Duval (Tenebrionidae, Coleoptera).]** *Ztschr. Vitamin-, Hormon- Fermentforsch.*, 1954, **6**, 1-24. [Zool. Inst., Munich.] English and French summaries.

Larvae of *Tribolium confusum* on a synthetic diet containing 20 per cent. purified casein and a mixture of vitamins reached the stage of pupation but showed high mortality unless an active

principle from yeast residues was added to the diet. This substance, known as factor U, appeared to be essential for normal pupation and development of the beetle. The activity of the yeast residue was increased by digestion with papain.

Further investigation of the growth requirement of the larvae showed that the amino-acids arginine, histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan and valine were necessary for development of the imago. Several highly purified diets were evolved, and addition of vitamin B₁₂, inositol and *p*-aminobenzoic acid to a satisfactory mixture did not improve growth or metamorphosis. With a basal diet containing vitamin-free casein and glucose, it was possible to use *Tribolium* larvae to test for the presence of vitamins of the B complex in casein and starch. It is suggested that the method could be adapted for estimating amino-acids.—A. M. Copping.

EMMICH, R. and PETZOLD, H. Tierexperimentelle Untersuchungen über die Wirksamkeit des "Leberparenchymfaktors". [Animal experiments on the activity of the liver-parenchyma factor.] *Ztschr. ges. inn. Med.*, 1954, **9**, 95-98. [2. Med. Klin., Martin Luther Univ., Halle-Wittenberg.]

Part of the liver was removed from rats of which some received intravenously for 3 days before the operation, and daily after it for 2 or 10 days, 0.017 or 0.0127 ml. of a liver hydrolysate, Prohepar, as a source of the liver-parenchyma factor; the doses were considered to be equivalent to 5 and 3.5 ml. per day for a 60 kg. man. These doses had no effect on liver histology or serum proteins of the intact animal. After partial removal of the liver, the larger dose produced fatty infiltration of the hypertrophied and regenerating residual liver tissue which was greater than in the animals receiving the smaller dose or none; the infiltration was very marked 2 days after the operation but had almost disappeared after 10 days. After the

operation all the rats showed a drop in the value for total serum protein due to a fall in albumin and α -globulin, which was greatest 2 days after the operation; the fall was greater in the treated animals than in the untreated. The changes in the other globulins were not significant. There was no difference in the blood findings for animals receiving the 2 doses.—L. Wills.

[Role of adenine (vitamin B₄) in the metabolism of organic substances and its effect on acid base equilibrium.] *J. Physiol., Paris*, 1954, **46**, 406-410. [Lab. Hôp. Saint-Germain-en-Laye.]

4542

MCDONALD, M. W. and MCCLYMONT, G. L. Studies on nutrition of poultry. 4. Nutritional value of condensed whale solubles in chicken rations. *Austral. Vet. J.*, 1954, **30**, 57-60. [Poultry Exp. Stat., Seven Hills, N.S.W.]

Condensed whale solubles containing 41 per cent. protein were compared with meatmeal in rations for chicks containing wheat and wheat products, minerals, synthetic riboflavin and vitamins A and D, with or without whey powder and alfalfa meal as a source of B vitamins other than riboflavin. When the solubles replaced part of the meatmeal in rations high in B vitamins, growth was significantly increased; when the rations were low in B vitamins the solubles had no growth-promoting effect. When the solubles replaced all the meatmeal in rations high in B vitamins, weight increase was similar to that of chicks receiving meatmeal, but when the ration was low in B vitamins, chicks receiving solubles grew poorly and 16 per cent. died. It is concluded that condensed whale solubles contain a protein as valuable as that of meatmeal, but that they lack a growth factor or factors supplied by meatmeal, alfalfa meal and whey powder.—E. M. Cruickshank.

VITAMIN C (ASCORBIC ACID)

4543

BACKE-HANSEN, K. and NORDAL, A. Jodometrisk bestemmelse av askorbinsyremholdet i torrede nyper. [Iodimetric estimation of ascorbic acid in dried rose hips.] *Dansk. Tidsskr. Farm.*, 1954, **28**, 53-63. [Stat. Farmacopélab., Univ. Oslo.] English summary.

An investigation of the methods for estimating ascorbic acid recommended in *Ph. Spec.* 46 showed that the oxidation of KI by dichlorophenolindophenol in H₂SO₄ required about 5 min. to reach

completion; the method of the *Ph. Dan.* 48 required reduction of the pH from about 3.5 to about 1 by the addition of 10 ml. 2N H₂SO₄. Details are given of the proposed modification of the Danish method. (From summary.)

TERENT'YEVA, E. L. Nekotorye dannye o khimicheskoi sostave askorbigena. [Some data on the chemical properties of ascorbigen.] *Bio-khimiya*, 1953, **18**, 296-301. [Kontrol. Vit. Stants., Moscow.]

Ascorbigen is unstable; a mercury derivative was found which was more stable, and could be stored without decomposition. Analysis of ascorbigen and of its mercury derivative showed it to contain 6 per cent. each of ascorbic acid and tryptophan, probably linked chemically. Two-dimensional paper chromatography of ascorbigen hydrolysates gave evidence for the presence of the amino-acids aspartic acid, glutamic acid, threonine, alanine, methionine, valine, leucine, arginine and histidine, already shown to be present by Pauli's reaction, and probably lysine. In addition two other amino-acids which were not identified were present on the chromatogram. The chromatographic method could be used to identify ascorbigen in biological material.—W. Hughes.

4546

DUDANI, A. T. and KRISHNAMURTI, C. R. Oxidation of ascorbic acid by terramycin. *Biochim. biophys. Acta*, 1954, **13**, 505-509. [Central Drug Res. Inst., Lucknow, India.] French and German summaries.

Of 6 crystalline antibiotics tested, only terramycin exerted any great catalytic effect on the oxidation of ascorbic to dehydroascorbic acid without liberation of CO_2 . The optimum pH was about 8. The activity was specific to ascorbic acid and was not found with numerous other reducing agents and chemicals of biological interest which were tested. The sample of terramycin used was free from trace metals, including Cu. Its activity was not affected by NaCN, glutathione, cysteine and other substances which inhibit the catalytic oxidation of ascorbic acid by Cu.—W. Godden.

NUMERS, C. V. The role of vitamin C in the mucopolysaccharide metabolism of the skin. Studies on free mucopolysaccharides and mast cells in the intact skin and during wound healing in normal and scorbutic guinea-pigs. *Ann. Med. exp. Biol. Fenn.*, 1953, **31**, 398-408. [Dept. Med. Chem., Univ. Helsinki.]

Fourteen guineapigs weighing from 450 to 600 g. were given a scorbutogenic diet, and on the 13th, 14th or 16th day a large piece of the cutis, subcutis and extensor thigh muscle was removed under anaesthesia. Half the animals were killed from 7 to 9, and in one case 16 days later, and the wound was excised. The other half were given 10 mg. ascorbic acid daily from about 5 days after the operation. After from 1 to 5 days' treatment they were killed and the wound excised. Four other animals received a normal diet and the same operational treatment. The skin and the excised tissues were examined histologically with appropriate staining.

In the scorbutic animals the number of mast cells in the corium was very low and did not increase in the wound areas as it normally should, but no morphological difference was detected in the mast cells. In the healing wound, the capacity of the fibroblasts to proliferate was impaired, and mucopolysaccharides could not be detected in connective tissue adjacent to the wound. Mucopolysaccharides were rare in the corium of normal and scorbutic guineapigs, but in the epidermis free mucopolysaccharides were more frequent in the scorbutic animals. The structure of the hair follicles, and consequently the production of hair, were not affected in scurvy.—E. M. Hume.

TURESKY, S. S. and GLICKMAN, I. Histochemical evaluation of gingival healing in experimental animals on adequate and vitamin C deficient diets. *J. Dent. Res.*, 1954, **33**, 273-280. [Dept. Oral Pathol., Tufts Coll. Dent. Sch., Boston, Mass.]

One group of guineapigs was fed on a complete diet and received in addition daily injections of 10 mg. ascorbic acid; two other groups received a diet free from vitamin C. After 14 days, when clinical signs of scurvy were evident in the deprived groups, the gums were cut back in each animal in the non-deprived group and in one of the deprived groups; gingival biopsy samples were obtained from each animal in the other deprived group on the 18th and 28th day. Specimens of healing gum tissue were obtained from the animals in which the gums had been cut 4, 7, 10, 14, 18, 20 and 21 days after the operation. Histochemical studies of all specimens showed that the formation and maturation of basement membrane,

the appearance and increase in amount of ground substance, and the formation of collagen fibres, all essential to normal gingival healing, were impaired in acute vitamin C deficiency.

W. Godden.

4551

LUDWIG, A. W. (with CHEN, D. K.) **Development of experimental exophthalmos in scorbutic guinea pigs.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 424-427. [Dept. Pathol., Med. Serv., Mount Sinai Hosp., New York.]

The thyroid gland was removed from one of 2 groups, each of 20 guineapigs. Nine days after the operation half the animals in each group was given a vitamin-C-free diet and the others continued on an adequate diet. After 18 days, when the animals on the scorbutogenic diet had lost an average of 69 g., all the thyroidectomised guineapigs received daily for 5 days intraperitoneal injections of 3 mg. of the thyrotropic fraction of the anterior pituitary gland. All the animals were then killed. Severe exophthalmos was present in all the thyroidectomised animals whether they had been deprived of vitamin C or not. The eyes of the intact animals, with and without scurvy, showed no change. The increase in the water and hexosamine content of the orbital tissues of the exophthalmic animals was as great in those with scurvy as in those fed on an adequate diet.—W. Godden.

4552

BURNS, J. J., MOSBACH, E. H. and SCHULENBERG, S. **Ascorbic acid synthesis in normal and drug-treated rats, studied with L-ascorbic-1- C^{14} acid.** *J. Biol. Chem.*, 1954, **207**, 679-687. [Res. Serv., Third (New York Univ.) Med. Div., Goldwater Mem. Hosp., New York.]

L-Ascorbic acid-1- C^{14} was administered to normal rats and rats which had received daily 45 mg. chloretone or 30 mg. pentobarbital. The specific activity of the urinary ascorbic acid was measured on successive days. From these values, the amount of the body pool and the turnover rate of ascorbic acid were calculated by the method of Feller *et al.* (Abst. 613, Vol. 21). The average body pool of ascorbic acid in the normal rats was 10.7 mg. per 100 g. bodyweight, in those receiving chloretone 19.2 and in those receiving pentobarbital 19.6. The amounts of ascorbic acid synthesised daily were 2.6, 21.5 and 11.6 mg. per 100 g. bodyweight, respectively, of which 15, 48 and 24 per cent. were recovered in the urine.

DE FELICE, F. **Sul significato delle correlazioni intervitaminiche. 1. Il contenuto di acidi l-ascorbico e deidro-l-ascorbico in alcuni organi di cavie C-carenzate e trattate con tiamina, o biotina, o acido p-aminobenzoico. [The significance of vitamin inter-relationships. 1. The content of l-ascorbic and dehydro-l-ascorbic acids in some organs of vitamin-C-deficient guineapigs treated with vitamin B₁, biotin or p-aminobenzoic acid.]** *Arch. Sci. biol., Bologna*, 1954, **38**, 113-118. [Ist. Fisiol. Umana, Univ. Bari.]

For previous results, see Absts. 3565, Vol. 21; 3013, Vol. 23; 529, Vol. 24.

Ascorbic acid and dehydroascorbic acid were estimated in 7 organs and tissues of normal guineapigs weighing from 230 to 260 g., and of 4 groups of from 20 to 30 similar animals maintained on a scorbutogenic diet and given daily, biotin 1 mg., or vitamin B₁ from 5 to 7 mg., or p-aminobenzoic acid 10 mg., or no supplement. Animals were killed at intervals up to the 35th day.

All the 3 vitamins retarded the rate of depletion of ascorbic acid, but the behaviour of dehydroascorbic acid was not consistent, the concentration showing some tendency to increase at first and decline later. All the results for individuals and tissues are tabulated.—E. M. Hume.

KHALIL, H. H. **Significance of ascorbic acid in the adrenal cortex.** *Lancet*, 1954, **266**, 912. [Dept. Pathol., Guy's Hosp. Med. Sch., London, S.E.1.]

Twenty rats weighing about 100 g. had the pituitary gland removed, after which 10 of them received daily, for 1 week, by injection, 100 mg. Na ascorbate in saline and the others saline only. They were then killed together with 10 normal, intact controls. The adrenal glands were removed and weighed immediately; their average weight in mg. per 100 g. bodyweight was for controls 25.0 ± 1.2 , for rats receiving Na ascorbate 21.8 ± 1.3 , and for rats receiving saline 12.2 ± 0.2 . Frozen sections of the adrenal glands showed that those from the hypophysectomised rats receiving ascorbic acid contained much less cholesterol than those from the other two groups.—W. Godden.

Der Einfluss des Systems Ascorbinsäure-Dehydroascorbinsäure auf die Biosynthese der Corticosteroide unter Berücksichtigung der Wasserstoffionenkonzentration. [Metabolism of the adrenal cortex and biosynthesis of corticosteroids. 6. Effect of the system ascorbic acid-dehydroascorbic acid on the biosynthesis of corticosteroids with reference to the hydrogen ion concentration.]** *Biochem. Ztschr.*, 1954, **325**, 288-294. [Zentrallab., Städt. Krankenanst., Mannheim.]

For details of technique see Abst. 3451, Vol. 24.

In buffered solutions of glucose in 0.9 per cent. saline, the synthesis of corticosteroids by slices of pig adrenal gland was increased by from 30 to 60 per cent. on addition of ascorbic acid in an amount equal to 1 per cent. of the weight of the adrenal slices, but only over the pH range from 6.3 to 6.6. The same was true for dehydroascorbic acid. The addition of ascorbic acid oxidase with ascorbic acid gave no increase at all in corticosteroid synthesis, although the oxidase alone caused an increase of from 40 to 70 per cent. after only 2 hours' incubation.—W. Godden.

4560

- BACCHUS, H. **Maintenance of blood 17-hydroxycorticosteroids following ascorbic acid treatment.** *Endocrinology*, 1954, **54**, 402-408. [Res. Lab., Dept. Physiol., Sch. Med., George Washington Univ., Washington, D.C.]

Two groups of adult male rats from which both adrenal glands had been removed were maintained on Purina chow and saline, and received single injections of 2 mg. cortisone acetate and 10 mg. Na ascorbate per 100 g. bodyweight, or the cortisone acetate and saline. Some animals were

killed before injection or 3, 24, 48, 72 or 96 hr. after injection. Plasma content of 17-hydroxycorticosteroids was estimated and blood leucocyte counts were made. Three hr. after injection the blood plasma values for 17-hydroxycorticosteroids were almost identical in both groups; after 24 hr. the level in the group given Na ascorbate was significantly higher than in the group without. The difference persisted up to 72 hr. but no corticosteroids were present in either group after 96 hr. The leucocyte counts showed that administration of Na ascorbate prolonged the haematological effect of cortisone acetate to 24 hr., but that the values had returned to those before injection after 48 hr. in both groups (*cf.* Abst. 4412, Vol. 23).—W. Godden.

It was previously shown (Abst. 587, Vol. 22) that cortisone had no effect on the sequence of events in the production of experimental scurvy or the early recovery from it, as evidenced by gross and histological changes. In the present work it was shown that the sera of guineapigs suffering from uncomplicated scurvy and given or not given cortisone did not differ in their abnormally high content of mucoprotein estimated as tyrosine or as glucosamine. When scorbutic guineapigs were recovering after being given 50 mg. ascorbic acid daily by mouth, the decline to normal of the mucoprotein concentration in the serum was more rapid if cortisone was administered concurrently. Cortisone tended to raise the already high values for serum cholesterol and lecithin in scorbutic guineapigs.—W. Godden.

4564

DESMARAIS, A. Fatigue expérimentale. [Experimental fatigue.] *Laval méd.*, 1954, **19**, 231-242. [Dept. Exp. Physiol., Fac. Med., Laval Univ.]

Tests for measuring fatigue in man are considered, and some experimental results are presented. As criterion, blood lactic acid values are rejected as measuring adaptation to effort rather than fatigue itself. Part of the MacQuarrie test for mechanical ability is considered to be applicable to the purpose.

Groups of white Wistar rats, 9 and 10 in one experiment, 19 and 21 in another, were subjected to 2 or 5 weeks' training by running in a revolving drum. One group in each experiment received 3 daily doses of 50 mg. Na ascorbate by mouth. At the end of training the animals were left to run to exhaustion and were then killed. Those given ascorbate did not become exhausted as soon as those not given it; the mean weights of their thymus glands were 13.7 and 15.5 per cent. less, and the mean succinic dehydrogenase content of the adrenal glands was 18.4 per cent. less (one experiment only). The weight of the adrenal glands was the same.—E. M. Hume.

DAVIDOV, R. B. and GUL'KO, L. E. O nekotorykh faktorakh, vliyayushchikh na sodержanie vitamina C v moloche. [Certain factors affecting the vitamin C content of milk.] *Uspekhi Sovrem. Biol.*, 1953, **35**, 457-464. [Moscow.]

Averages for the ascorbic acid content of milk round the year for a group of test animals were from 13 to 16 mg. per litre with range from 7 to 23 mg. The value changed during the day with a maximum in the evening which was 20 per cent. above that in the morning in summer and 50 per cent. above it in winter. The value in winter was from 30 to 40 per cent. higher than in summer. The minimum values recurred in the period from June to August. During the first 2 or 3 months of lactation the value increased and then fell towards the eighth month; during the last month of lactation there was another slight rise. These changes were not seen in animals that were not also pregnant. (From summary.)—W. Hughes.

CHRISTENSEN, E. V. and TERP, P. Om C-vitamin-indholdet i solbørsaft. [The vitamin C content of blackcurrant juice.] *Arch. Pharm. Chem.*, 1954, **61**, 69-90. [Dan. Apot. Kontrollab. Oxford allé Apotek.] English summary.

The fermentation of the sugar during the process of producing blackcurrant juice did not

N.A. and R., October 1954

lower the vitamin C content. The skin of the fruit should be broken down by a suitable pectinase preparation in order to obtain the ascorbic acid contained in it. Implements of tin, copper and iron, except stainless steel, should be avoided and the action of air reduced to a minimum. With these precautions a juice containing nearly 0.2 per cent. ascorbic acid was produced. The vitamin was best preserved by storage in completely filled bottles; not more than 30 per cent. was then lost in 12 months. Stability was not increased by heating the juice to 100° C. (From summary.)

MINIERI, L. Acido ascorbico totale in alcune ghiande della Campania. (Ricerche col nuovo metodo Tillmans-Ott.) [Total ascorbic acid in some acorns of Campania. Study with the new method of Tillmans and Ott.] *Zootec. Vet.*, 1954, **9**, 104-106. [Ist. Zootec. Gen., Univ. Naples.] French and English summaries.
In some of the central provinces of Italy the

acorns of the common oak and evergreen oak are used in the fattening of pigs and are given to other animals. Ascorbic acid was estimated by indophenol titration in the nuts and cups from oak trees in several localities. The mean value in mg. per 100 g. fresh tissue ranged from 5 to 8 for the acorn nuts and from 16 to 20 for the cups. It is recommended that the cups should be included in the feed in spite of their large content of fibre.

CREAC'H, P. V. and BARAUD, J. L'acide ascorbique total dans les algues marines. [Total ascorbic acid in marine algae.] *C.R. Soc. Biol.*, 1954, **148**, 105-107. [Lab. Biochim., Inst. Sci. Pêches Maritimes.]

With the method previously described (Abst. 556, Vol. 22), a number of different species of green, brown and red seaweeds were analysed for total ascorbic acid. The amount found ranged from 2.76 to 135.0 mg. per 100 g. fresh tissue or from 46.3 to 515.0 mg. per 100 g. dry matter.

TOLCKMITT, W. Zur Frage des Magenkathepsins. [Stomach cathepsin.] *Biochem. Ztschr.*, 1954, **325**, 389-400. [I. Klin. Med., Univ. Hamburg, Eppendorf.]

The curves of proteolytic activity of gastric

juice, with acetic, lactic, tartaric and hydrochloric acids and 2 buffer solutions, in every case, over the pH range used by Buchs, had a single peak. Buchs in his experiments used HCl up to pH 2.2 and acetic acid for the higher range, and the depression in his curve occurs exactly at the point where acetic acid was introduced into the pH scale. The double peak obtained by Buchs may be due to his use of 2 different acids, and not, as he infers (*Die Biologie des Magenkathepsins*, 1947, S. Karger Verlag, Basle) to the presence of 2 different enzymes. The presence of a catheptic stomach enzyme cannot yet be regarded as certain.

M. B. Richards.

BUCHS, S. Über das Duodenalpepsin und das Duodenalkathepsin der Tiere. [**The duodenal pepsin and duodenal cathepsin of animals.**] *Pflügers Arch.*, 1953-54, **258**, 304-310. [Kind-erlin., Univ. Basle.]

Extracts of upper duodenal mucosa from cats, cattle, dogs and pigs showed pH activity curves similar to those of gastric juice or extracts of gastric mucosa. All 3 curves showed a double peak. Proteolysis occurred from pH 1 to about pH 4. The digestion of the substrate is ascribed to pepsin and cathepsin in the duodenal mucosa.

BOTHWELL, J. W. and WILLIAMS, J. N. (Jr.) **Effects of a lysine deficiency upon enzyme activity in rat liver.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 544-547. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Male weanling rats were fed, either to appetite or forcibly by stomach tube, on an amino-acid diet with or without lysine. When animals showed signs of lysine deficiency they and corresponding controls were killed and some enzyme activities of the liver were measured. The endogenous respiration was unaffected by lysine deficiency; the activity of xanthine oxidase per g. liver N decreased to about 60 per cent. of that of controls, and succinic oxidase and choline oxidase to about 71 per cent. The reduction of activity was similar for animals fed forcibly or at will, even though the latter ate less of the lysine-deficient diet. The results are compared with those of earlier work (Absts. 4910, Vol. 19; and 3593, Vol. 21) which showed that methionine deficiency almost abolished, but histidine deficiency had no effect on, xanthine oxidase activity.—C. Warner.

4582

LITWACK, G., FATTERPAKER, P., WILLIAMS, J. N. (Jr.) and ELVEHJEM, C. A. **Studies on the response of liver xanthine oxidase to dietary protein in weanling rats.** *J. Nutrition*, 1954, **52**, 187-197. [Dept. Biochem., Univ. Wisconsin, Madison.]

The experiments described in Absts. 473 and 4592, Vol. 23 are here extended to the study of enzyme response and growth response in the same animals. Enzyme and growth results agreed fairly closely when casein, lactalbumin, gliadin or a maize and soya mixture was the source of protein. Autoclaving with dilute alkali to destroy vitamin B₁₂ enhanced the xanthine oxidase response greatly and the growth response less. The enzyme responses to casein, alkali-treated casein and gliadin were slightly increased when vitamin B₁₂ was included in the diet. The addition of

molybdate to the lactalbumin diet had no effect on the enzyme response.—C. Warner.

WAINIO, W. W., ALLISON, J. B., EICHEL, B., PERSON, P. and ROWLEY, G. R. **Enzymes in protein depletion. 2. Oxidative enzymes of heart ventricle.** *J. Nutrition*, 1954, **52**, 565-573. [Bur. Biol. Res., Rutgers Univ., New Brunswick, N.J.]

For part 1 see Abst. 4431, Vol. 23. The diets and treatment of the rats resembled those in the previous experiment.

The activities of succinic dehydrogenase, DPN-cytochrome c reductase and cytochrome oxidase in heart muscle were not significantly affected by protein depletion or by food restriction. Total enzyme activity was directly related to the amount of total protein in the heart, in contrast to the condition in the liver reported earlier.

RINDI, G. **Comportamento della glutamico-ossalacetico transaminasi di tessuti di ratto in seguito a surrenectomia e a trattamento con ormoni corticosurrenali.** [**Behaviour of glutamic-oxaloacetic transaminase in the tissues of rats after adrenalectomy and treatment with adrenal cortical hormones.**] *Arch. Sci. biol., Bologna*, 1954, **38**, 155-171. [Ist. Fisiol. Umana, Univ. Pavia.]

Adrenalectomy in the rat reduces the activity of the glutamic oxaloacetic transaminase of the heart, muscle and brain, but does not significantly affect that of the liver. Injections of cortisone restore to normal the transaminase activity of heart and brain, and raise above normal that of muscle and liver. Deoxycorticosterone acetate (DOCA) has no influence on the glutamic-oxaloacetic transaminase of liver, heart and brain, but restores to normal that of the muscle. In the normal rat cortisone increases only the glutamic transaminase of the liver, leaving that of the other tissues unaltered; DOCA has no clear action on any of the tissues studied, although it tends to reduce the transaminase activity of the liver.

GREENBAUM, A. L. and GREENWOOD, F. C. **Some enzymic changes in the mammary gland of**

N.A. and R., October 1954

rats during pregnancy, lactation and mammary involution. *Biochem. J.*, 1954, **56**, 625-631.

[Dept. Biochem., University Coll., London.]

Nine groups of rats were used; 3 were killed on the 10th, 15th and 20th days of pregnancy, 4 on the 5th, 10th, 15th and 20th days of lactation and 2 on the second and fourth days of involution of the mammary gland after removal of the young at 21 days of age.

Glutamic dehydrogenase activity in the mammary gland rose significantly in the last third of pregnancy, remained high during lactation and fell steeply during involution. It was about one-tenth that of liver. For glutamic-aspartic transaminase activity there was during pregnancy a slow increase, at parturition a rise to a high level which was maintained throughout lactation and during involution a rapid decrease. The activity was about one-third that of liver. Cathepsin activity increased only slightly during pregnancy but rose steadily during lactation, and the rise continued during involution. It was greater than in any other tissue and twice that for lymph nodes, the most active tissue recorded. β -Glucuronidase activity rose sharply between the 15th and 20th days of pregnancy, fell during lactation and rose to its highest level during involution. It was about one-third that of liver.

The results are discussed in relation to changes that may occur in the mitochondria during the lactation cycle.—D. Harvey.

MORRISON, M. A., McLAREN, B. A. and STADELMAN, W. J. Characteristics of a fatty acid oxidase from adipose tissue of the hen. *Poultry Sci.*, 1954, **33**, 401-406. [Agric. Exp. Stat., State Coll. Washington, Pullman.]

Adipose tissue was taken from the backs, thighs and visceral cavities of hens. The fat was expressed from the tissue and the residue was homogenised in a phosphate/MgSO₄ buffer. The capacity of the preparation to oxidise fatty acids was tested in a Barcroft Warburg apparatus.

The enzyme system was inactive before it was incubated at 37° C. for 18 to 24 hr. The incubated preparation, after filtration, oxidised octanoic, myristic, palmitic, stearic, oleic and linoleic acids. Oxidation was completely inhibited by NaCN, hydroxylamine hydrochloride and arsenite; malonate and K ferricyanide had no effect. Oxidation was partly inhibited by Na azide and Na diethyldithiocarbamate. The anti-oxidants nordihydroguaiaretic acid and propyl gallate slightly reduced the oxygen uptake in the oxidising system when oleic and myristic acids were the substrates.

DIGESTION AND ABSORPTION

X-ray examinations numbering 63 were made of the small intestines of infants aged 14 days to 1 year, the BaSO₄ being mixed with different diets such as tea, human milk, two-thirds milk, buttermilk, mixed human and buttermilk, gruels and vegetable soups. For any one food there was close similarity among the infants in the X-ray pictures obtained, but distinct differences were obtained with different food mixtures. Tables are

given showing the nature of the picture obtained and times of passage for the different diets. The line between normal and pathological X-ray findings in the small intestine must not be drawn too sharply; a certain amount of variation is to be regarded as physiological. Some of the findings reported in the literature as pathological have in the present investigation been found in healthy infants.—M. B. Richards.

4597

BRUMMER, P. and YLI-POHJA, M. **On the significance of peptic digestion.** *Acta med. scand.*, 1954, **148**, 239-244. [Med. Clin., Turku Univ.] The glycine test was used to test peptic digestion

in 21 subjects suffering from achlorhydria, in 20 subjects after subtotal gastrectomy and in 20 normal subjects. The test consists in administering 1.5 g. gelatine in 30 ml. warm water per kg. bodyweight. Venous blood is collected after 2, 3 and 4 hr. and the plasma glycine content is estimated.

No difference was found in the rise in plasma glycine between the achlorhydric group and the controls. Subjects in whom subtotal gastrectomy had been performed showed a somewhat greater rise in plasma glycine. The results indicate no difference in protein digestion in subjects suffering from achlorhydria. The increased response after subtotal gastrectomy is probably due to a more rapid emptying of the stomach, so that the gelatine comes into contact with trypsin more rapidly than normal.—A. T. Phillipson.

PALOHEIMO, L., MÄKELÄ, A. and SALO, M. L. **Some observations on the transport of food in the alimentary canal of the rat.** *Maataloust. Aikakausk.*, 1954, **26**, 1-9. [Dept. Animal Husb., Univ. Helsinki.] Finnish summary.

Work on the transit of food through the digestive tract of simple-stomached mammals is briefly reviewed.

Adult rats of both sexes were given an experimental meal of dried wheat bread containing milk, sugar, cocoa fat, yeast and salt. The size of the meal was positively correlated with the amount removed from the stomach in the first 3 hr.

In rats killed 5 min. after beginning to feed, food had already traversed about 60 per cent. of the small intestine, but the rate of passage then declined sharply, and passage through the ileo-caecal valve did not occur until 90 min. after the start of the meal.

The results do not support the classical concept of peristalsis as expressed by Bayliss and Starling. D. Duncan.

LE BARS, H., NITESCU, R. and SIMONNET, H. *Recherches sur la motricité du rumen chez les petits ruminants. [Investigation of the motility of the rumen in small ruminants.]* 1. Motricité normale. [1. Normal motility.] 2. Relation entre la motricité et la glycémie. [2. Relation between motility and blood sugar.] 3. Action de l'adrénaline. [3. Action of adrenaline.] *Bull. Acad. vét. France*, 1953, **26**, 287-300; 351-360; 445-447. [Lab. Physiol., École Nat. Vét., Alfort.]

1. The movements of the rumen in adult sheep were recorded graphically from a portion of the rumen brought by operation into permanent adherence to the overlying skin, or by creation of a rumen fistula through which a balloon could be introduced. The methods gave concordant results. The tracings obtained are reproduced.

As soon as the animal began to masticate its feed, whatever the feed might be, the normal contractions of the rumen at rest became more rapid; when eating ceased they became slow again. During rumination the frequency of contraction was intermediate between that of eating and that of rest. At the moment of regurgitation the rumen did not contract, but it contracted as soon as mastication began. Eructation of gas was always accompanied by two contractions close together.

2. The changes in blood sugar in relation to the contractions of the rumen were studied by the method with a rumen fistula; glucose or insulin was given intravenously. It is clear, when allowance was made for a certain latent period, that high blood sugar inhibited contraction of the rumen and low blood sugar promoted it.

3. By the same methods, intravenous injection of adrenaline was found to cause immediately almost total inhibition of contraction lasting for 1 or 2 min.; for the next 2 min. contraction returned, but inhibition then set in again and lasted for about 3 hr.—E. M. Hume.

Vol. 24, No. 4

4603

WELLER, R. A. and GRAY, F. V. **The passage of starch through the stomach of the sheep.** *J. Exp. Biol.*, 1954, **31**, 40-48. [Div. Biochem., C.S.I.R.O., Univ. Adelaide, S. Austral.]

The quantities of polysaccharide estimated as starch passing to the abomasum were calculated from the starch:lignin ratios of the ruminal and abomasal contents. When sheep received diets containing from 3 to 149 g. starch it was estimated that from 1 to 8 g. passed through the abomasum in 24 hr.

Some evidence is presented which suggests that of the total polysaccharide material estimated as starch about two-thirds was contained in the protozoa. Counts of the protozoa in the different parts of the stomach show that they are much reduced in numbers in the omasal contents. Microscopic examination of omasal contents revealed signs of death of those organisms in the omasum.—A. T. Phillipson.

4604

GRAY, F. V., PILGRIM, A. F. and WELLER, R. A. **Functions of the omasum in the stomach of the sheep.** *J. Exp. Biol.*, 1954, **31**, 49-55. [Div. Biochem., C.S.I.R.O., Univ. Adelaide, S. Austral.]

Lignin and total dry matter are concentrated in the omasum. This could be due to contraction of the organ and pressure of the liquid part of the digesta into the abomasum or reticulum, but examination of the nitrogen:lignin ratio of the digesta in different parts of the stomach did not support this view. The ratio is greater in the reticulum digesta than in the omasal and abomasal digesta, in which it is similar. This indicates not only that little fluid is expressed from the omasum, but also that little direct passage from the reticulum to the abomasum occurs. On the assumption that both are of negligible proportions it is calculated from the lignin concentrations that 33 to 64 per cent. of the water entering the omasum is absorbed. The fatty acid:lignin ratios show that 40 to 69 per cent. of these acids entering the omasum are absorbed.—A. T. Phillipson.

STEINBECK, A. W. **Plasma and blood volumes of normal Australian females.** *Austral. J. Exp. Biol. Med. Sci.*, 1954, **32**, 95-99. [Dept. Med., Univ. Sydney.]

Plasma volume was estimated by the T-1824 method in 35 normal women; details of technique were as before (Abst. 533, Vol. 21). Results from a 30-min. disappearance curve did not differ significantly from those from a full disappearance curve. Individual results are tabulated and linear regression equations are given for plasma volume on bodyweight, height, surface area, and bodyweight and height. Mean values were 48.23 ± 0.87 (S.E.) ml. per kg. bodyweight, 16.70 ± 0.34 ml. per cm. height and 1.687 ± 0.265 litre per sq.m. surface. When plasma volume was re-estimated in 6 of the subjects after 6 months, the results were close to the original values.

W. M. Deans.

4621

BURKE, J. D. **Blood volume in mammals.** *Physiol. Zool.*, 1954, **27**, 1-21. [Univ. Florida.]

Blood volume was estimated with red blood cells labelled with ^{32}P and with T-1824. Red cells were counted and Hb concentration was measured.

In 14 opossums, *Didelphis virginiana pigra*, values for total plasma volume, total red cell volume and total blood volume were somewhat higher by the dye method. Withdrawal of serial samples showed that mixing was complete within 1 min. of injection for both methods. Within an hour the percentage of dye in the blood had decreased to 79.8, and of radio-activity to 80.8. Blood volume was estimated also in 10 Duroc-Jersey pigs of different weights; mixing was complete in 10 min. The mean values in ml. blood per 100 g. bodyweight by the dye and radio-active methods, respectively, were 5.83 and 5.49 for the opossums and 8.16 and 7.96 for the pigs. The blood volume relative to bodyweight within the species was less as bodyweight increased; the relative blood volume in young animals was thus greater than in older ones.

Values from the literature are tabulated for many animals.—E. M. Hume.

STANIER, M. W. and THOMPSON, M. D. **The serum protein levels of newborn African infants.** *Arch. Dis. Childhood*, 1954, **29**, 110-112. [Dept. Physiol., Makerere Coll., Kampala, Uganda.]

Two sets of data are presented for serum proteins as measured by the Antweiler micro-electrophoretic apparatus.

The first gives means and ranges for 14 samples of cord blood and for 10 of maternal blood. For cord blood the level of albumin was above and the levels of β - and γ -globulin were below those for maternal blood by amounts statistically significant. For comparison with white subjects the data of Longworth *et al.* (Title 14, Vol. 15) are quoted. In the cord blood of Africans levels of albumin and β -globulin were considerably lower and in maternal serum all proteins except γ -globulin were also significantly lower than in the American samples. The γ -globulin in African mothers' was about twice that in white mothers' blood.

The second set of data refers to 5 infants whose cord blood was analysed and from whom blood samples were obtained at 8, 9 and 12 days and 12 weeks and 12 weeks, respectively. No increase in γ -globulin was found in these infants during early life.—D. Harvey.

4623

JASO, E., ITURRIAGA, E. and ROLDÁN, A. **Alteraciones de las proteínas plasmáticas en el curso de los trastornos [? trastornos] nutritivos del lactante. [Changes in plasma proteins during digestive disturbances in the infant.]** *Rev. española Pediat.*, 1954, **10**, 213-220. [Madrid.] French, English and German summaries.

Protein fractions were estimated, by the method of free electrophoretic migration in Kern's apparatus, in plasma of 17 infants, 9 suffering from toxicosis and 8 from dystrophy. In both groups there was a distinct increase in the α -globulin fraction, especially in the α_2 -form, and in γ -globulin, the increase in the latter being more marked in the dystrophic. Such changes are attributed to a hepatic lesion in the state of toxicosis, which affects both the hepatic cell and the interstitial tissue. In dystrophy the protein syndrome corresponds to that of chronic malnutrition.

M. B. Richards.

CAREDDU, P. and VULLO, C. **Risultati di indagini elettroforetiche e di prove immunitarie e di labilità colloidale nell'anemia mediterranea. [Results of electrophoretic study and of tests of immunity and of colloid lability in Mediterranean anaemia.]** *Riv. Ist. sieroterap. ital.*, 1954, **29**, 182-189. [Clin. Paediat., Univ. Sassari.] English summary.

In 20 children with Cooley's (Mediterranean) anaemia total serum protein was normal, albumin low except in 6, γ -globulin high in all but 1 and the albumin:globulin ratio was reversed. There was no evidence of immunological abnormality.—I. Leitch.

4625

BUSSON, F., TRAPET, P. and LECOCQ, F. Exploration des protéines sériques. Application aux sérums d'Africains de Dakar. [Investigation of serum proteins. Application to serum of Africans in Dakar.] *Méd. trop.*, 1953, 13, 977-1001. [Org. Enquête Étude Anthropol. Pop. Indigènes A.O.F. Aliment. Nutrit.]

Methods are reviewed for fractionating serum proteins, and a detailed description is given of electrophoretic, paper chromatography and spectrophotometric methods used by the authors. Spectrophotometric estimations were usually made because the method was rapid, but the results, especially those from abnormal sera, were frequently checked against those obtained by electrophoresis.

Values for Europeans and Africans are given; those for Africans showed the expected high value for total serum protein, a moderately low one for albumin and a greatly increased one for γ -globulin, compared with findings for Europeans. The mean albumin:globulin ratio for 48 healthy Europeans was 1.23 with S.D. 0.16, and for 375 apparently healthy Africans 0.78 with S.D. 0.17. Serial studies still in progress suggested a seasonal variation in the serum proteins of Africans.

4626

ARENS, L. and BROCK, J. F. Some aspects of the serum protein pattern of Africans. *S. African J. Clin. Sci.*, 1954, 5, 20-34. [Dept. Med., Univ. Cape Town.]

The methods used by Holmes *et al.* (Abst. 678, Vol. 22) in Kampala were employed in Cape Town to study the serum proteins of 100 African labourers; "liver function" turbidimetric tests were also made on some of the subjects. Twenty healthy Europeans in Cape Town acted as controls for comparison with these Africans and with the Europeans in the Kampala study. In addition blood samples were obtained from 65 Africans in South-West Africa and Southern Rhodesia, both areas of endemic tropical disease; the 7 subjects in Rhodesia were known to have schistosomiasis.

For the data for Europeans no statistical comparison was possible, but results appeared comparable with those obtained by Holmes and co-workers. For the Africans in Cape Town total protein, albumin, total and β -globulin were higher and α - and γ -globulin lower on the average than for Kampala Africans. Comparison of the Africans

with the Europeans in Cape Town showed significant differences in all protein fractions. The Europeans could be regarded as healthy, but the Africans were only apparently so. By a more strict selection which excluded those with abnormal red blood sedimentation rates or turbidity reactions the Africans were reduced to a group of 9 "rigorous normals", but the values for them, although nearer those for Europeans, were in most respects outside the European range. In general the results of the liver function tests showed abnormality for the Africans and were negative for the Europeans.

It is concluded that, while the presence of parasitic infestation may to some extent account for these differences between the serum protein fractions in Africans and Europeans, prolonged protein malnutrition and latent liver disease may also be responsible.—D. Harvey.

OEFF, K. Umsatz von radioaktiven Serum-eiweissfraktionen. 1. Methodische Grundlagen. 2. Versuche an normalen Ratten. [Turnover of radio-active serum protein fractions. 1. Technical principles. 2. Experiments on normal rats.] *Ztschr. ges. exp. Med.*, 1954, 123, 294-308; 309-314. [Med. Klin., Freie Univ., Berlin.]

1. To investigate the turnover of the separate protein fractions in human and animal sera, ^{131}I was used to label proteins. The procedure is described in detail.

2. The activity of serum and its protein fractions was studied in rats after injection of rat serum labelled with ^{131}I . The curves of the fall of activity in total protein and in separate fractions showed 2 phases, the rapid fall in the first phase representing the mixing of the injected protein molecules with the extravascular protein reserve. The half-life of injected protein was 3 to 5 hr. The ratio of extravascular to intravascular protein was approximately 4:1. The second phase of the curves represented the rate of turnover of the proteins. The half-life of total serum protein was 2.4 days, of albumin 2.7 days, and of separate globulin fractions 2.0 to 2.4 days. The daily turnover of plasma protein was calculated to be about 0.76 g.—M. B. Richards.

[Blood chemistry in acute progressive arteriosclerosis. Electrophoretic estimation of lipoprotein in atheroma and atherosclerosis.] *Deutsch. med. Wochenschr.*, 1954, 79, 653-657. [Allg. Krankenhaus Barmbek, Hamburg.]

N.A. and R., October 1954

A simple method is described by which serum lipoproteins were separated by paper electrophoresis, stained with oil-red O and estimated colorimetrically. The lipoprotein picture was compared with the serum protein picture in circulatory disorders. Observations were made on normal subjects and on 166 patients with early acute cardiac infarction, 52 with threatened or receding cardiac infarction, 68 with slowly advancing softening of the brain and 22 with diabetes.

The blood protein picture was confused in acute progressive arteriosclerosis, but the lipoprotein picture was characteristic, particularly in the transference of lipid from α_1 - to β -protein, as shown by the high β -lipoprotein and low α_1 -lipoprotein levels and high $\beta : \alpha_1$ ratio, which were not accompanied by corresponding changes in the globulins. All the groups of patients showed these changes, but, if this method is used for diagnosis of early arteriosclerosis, liver disease must be excluded.

1. A semi-micro spectrophotometric method was used to estimate the serum dienoic, trienoic, tetraenoic and hexaenoic fatty acids in 93 well nourished infants and children.

The values obtained were all of the same order and were dienoic acids 27 to 30, trienoic acids 1-3 to 1-5, tetraenoic acids 9 to 10, and hexaenoic acid 3 to 4 per cent. of the total serum fatty acids. There appeared to be slightly less dienoic and tetraenoic acids in the sera of infants than in children 2 to 15 years old.

2. Levels of dienoic, tetraenoic and hexaenoic fatty acids in the sera of 57 poorly nourished children were significantly lower than in healthy, well nourished children, but the trienoic acid content was significantly higher.—G. A. Garton.

BARGETON, D., KRUMM-HELLER, C. and TRICAUD, M. E. Influence de d'âge et d'un acétate substitué sur le cholestérol sérique chez le rat. [Effect of age and of a substituted acetate on serum cholesterol in the rat.] *C.R. Soc. Biol.*, 1954, **148**, 63-65.

Two experiments were designed to investigate the variation with age of blood cholesterol in the rat, and the effect upon it of an acetate administered orally.

In the first experiment the level was seen to be dependent on age, as represented by bodyweight, in such a fashion that the points could be split into 2 groups, each giving a significant linear regression upon age and the group means not differing significantly from linearity. In animals between 100 and 250 g. weight, i.e., from 6 to 11.5 weeks old, the level fell with age; in older animals it rose again.

In the second experiment sodium phenylethyl-acetate was administered by mouth daily to 184 rats. Amongst these, blood cholesterol was independent of age and was at a level not significantly different from the lowest value in the untreated rats.

It was concluded that the value of 58 mg. per 100 ml. obtained at 11.5 weeks was an absolute minimum cholesterol level below which the average could not fall either as a result of age or by artificial interference with its metabolism as in the second experiment.—A. W. Boyne.

DURHAM, J. R., COOKE, R. E., LANCASTER, J. W. and MAN, E. B. **Serum butanol-extractable iodine values of children under ten years of age.** *Amer. J. Dis. Child.*, 1954, **87**, 468-474. [Dept. Int. Med., Sch. Med., Yale Univ., New Haven, Conn.]

From a study of 40 normal children aged 2 to 10 years the normal range of serum butanol-extractable I was found to be 4.5 to 7.3 μ g. per 100 ml. Of 56 children suffering from malnutrition, physical or mental retardation, mongolism, obesity, diabetes or hypertension, 41 had values within the normal range. Only undernutrition seemed to play a role in decreasing butanol-extractable I values. None of these children was clinically hyper- or hypothyroid.

Data are briefly quoted to show that values much above the normal range were obtained in 5 hyperthyroid children and very low values in hypothyroid children.—F. C. Aitken.

- HATTYASY, D. **Unusually high fluorine values in the saliva of subjects free from caries.** *Acta med. hung.*, 1954, **5**, 419-420. [Dept. Stomatol., Med. Sch., Univ. Szeged.]

Saliva which was pooled from 10 gypsies aged between 12 and 19 years, members of a community with a low incidence of caries, was found to contain 74 μg . F per 100 ml. Single samples from 8 persons between 8 and 15 years of age with extensive tooth decay had F contents between 5.4 and 13.1 with a mean of 8.0 μg . per 100 ml. Both groups were consuming water low in F, 20 μg . per 100 ml.

It is suggested that the high concentration may inhibit acid formation by bacteria and block enzyme activity and so limit caries production. The work is being extended.—D. Harvey.

SIMMONDS, D. H. **The amino acid composition of keratins. 1. The amino acid analysis of merino 64's quality virgin wool.** *Austral. J. Biol. Sci.*, 1954, **7**, 98-110. [Biochem. Unit, Wool Textile Res. Lab., C.S.I.R.O., Mel-bourne.]

The published data on the amino-acid composi-tion of wool are summarised. The technique of Moore and Stein (Abst. 4469, Vol. 21) was used for analysis of a single sample of merino wool and data for 18 amino-acids are tabulated. Two peaks of doubtful identity are the subject of further investigation. The value for glycine is less than that reported by Block (Title 1804, Vol. 9) and the cystine plus methionine S fell short of the total 3.68 per cent. by 0.51 per cent.—D. Harvey.

See also Absts. 4111, 4382, 4907, 5189.

ganic, ammoniacal or non-ammoniacal, pigment was formed in a ring round the nipples. In the neighbourhood of this areola the hair follicles were increased and arranged in 3 to 6 rows, instead of in a single row as in untreated rabbits, and the hair follicles of the lower layers were richer in pigment than those of the upper layers. The increase of hair follicles is ascribed to increased function of the adrenal cortex, but the increased pigmentation to increased melanophore hormone formation by the anterior pituitary. It is sug-gested that the skin pigmentation in pregnancy and in Addison's disease is also to be ascribed to increased melanophore hormone formation. The results are considered important not only from the standpoint of therapy, but also because of their possible practical bearing in the production of fur and wool.—M. B. Richards.

ENGFELDT, B. and ZETTERSTRÖM, R. **Biophysical and chemical investigation on bone tissue in experimental hyperparathyroidism.** *Endocrinology*, 1954, **54**, 506-515. [Dept. Phys. Cell Res., Karolinska Inst., Stockholm.]

Rats 1, 2, 4 and 8 months old were given by subcutaneous injection 1 U.S.P. unit of parathyroid extract per g. bodyweight for 20 days; 17 hr. after last injection, 0.15 or 0.30 mC. ^{32}P was administered as Na_2HPO_4 . The animals were killed 2 hr. later and the specific activity of bone orthophosphate was measured with an electronic counter.

In the two youngest groups of rats the relative specific activity of bone phosphate was diminished. In 4-month-old rats there was no change, and in 8-month-old rats there was increased activity. The differences in reaction of different age groups to parathyroid hormone should be kept in mind when interpreting experimental results.

After a single dose of parathyroid hormone no effect on renewal rate of bone phosphate could be detected at 6 or 12 hr.; there was a decrease after 18 hr., which persisted at 45 hr. but diminished at 73 hr. and disappeared by 96 hr.

Microradiographs and autoradiographs of cross-sections of bone tissue from young normal and parathyroid-treated dogs were prepared. The bones of the parathyroid-treated dogs showed many large resorption cavities and Haversian systems with low mineralisation, but there was also rebuilding of bone tissue in both groups. The bone destruction in the parathyroid-treated dogs was not different from the normal in type, but only in extent and acceleration.

There is some evidence that the primary effect of the hormone is on the organic or cell constituents of bone.—B. W. Simpson.

TALMAGE, R. V. and KRAINTZ, F. W. **Immediate changes in phosphate excretion following parathyroidectomy in the rat.** *Proc. Soc. Exp. Biol.*

Vol. 24, No. 4

Med., 1954, **85**, 416-419. [Dept. Biol., Rice Inst., Houston, Tex.]

Rats of 180 to 225 g. were used in these studies; 55 had their parathyroids removed and were given about 7 μC . ^{32}P intraperitoneally, usually 1 hr. after the operation, and water equivalent to 5 per cent. of the bodyweight. They were then placed in metabolism cages and urine was collected hourly or 3-hourly. Experiments ended 3, 7, 11 or 13 hr. after parathyroid removal, when blood was withdrawn for estimation of serum Ca and P.

Parathyroid removal consistently produced an immediate and marked drop in P excretion as shown by excretion of ^{32}P and total inorganic P. Out of 55 rats none failed to show a decrease. By an hour after the operation the effect on the kidney reached its maximum. When parathyroid extract was administered subcutaneously 2 hr. after the operation the rapid fall in P excretion was dramatically reversed.

The reliability of ^{32}P values as an indication of phosphate excretion was tested. A comparison was also made of P excretion rates with serum Ca and P. Although the urinary excretion of P fell within 1 hr. after operation, serum Ca and P changed more gradually; the serum P rise was not significant till the 7th hour. Serum Ca dropped faster than serum P rose. Despite injection of CaCl_2 and Na_2HPO_4 into the parathyroidectomised rats urinary P remained low. It is concluded that in the rat the parathyroids control P and Ca metabolism by a direct action on kidney excretion of P.—B. W. Simpson.

LOTZ, W. E., TALMAGE, R. V. and COMAR, C. L. **Effect of parathyroid extract administration in sheep.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 292-295. [Univ. Tennessee—Atomic Energy Commission Agric. Res. Program, Oak Ridge.]

Subcutaneous injection of parathyroid extract into sheep caused a rise in serum phosphate, the reverse of its effect in dog, rat and man. Urinary excretion of phosphate was only twice normal, small compared with the 30-fold increase produced in rats. Phosphate removal from bone was much increased. The parathyroid extract had no significant effect on Ca metabolism.—T. D. Bell.

ERSHOFF, B. H. **Protective effects of liver in immature rats fed toxic doses of thiouracil.** *J. Nutrition*, 1954, **52**, 437-455. [Emory W. Thurston Labs., Los Angeles, Calif.]

Weanling rats received a synthetic diet with vitamin supplement. Thiouracil added at a level of 0.1, 0.25 or 0.5 per cent. retarded growth and caused large increases in thyroid weight. Supplements of the known B vitamins or of alcohol-extracted casein did not influence the effect of thiouracil, but 10 per cent. dried liver produced almost normal growth and resulted in thyroids half the weight of those in rats not given thiouracil. The protective value of different samples of dried liver varied greatly; 3 out of 7 improved growth and only one, a sample with a high iodine content, prevented increase in thyroid weight. Dried kelp as a source of iodine was without effect on the response to thiouracil. Dried thyroid included at 500 mg. per kg. diet had a value similar to that of the most effective liver sample.—D. Duncan.

BUXTON, J., GRUNDY, H. M., WILSON, D. C. and JAMISON, D. G. **The absence of anti-thyroid properties for rats in two types of groundnut oil in common use in Nigeria.** *Brit. J. Nutrition*, 1954, **8**, 170-172. [Lab. Human Nutrit., Univ. Oxford.]

Groundnut oil is a common food in the Northern Territory of Nigeria. There are 2 kinds, an

indigenous oil extracted by hand from the groundnuts by a traditional method, and an unrefined crude oil extracted by machine. These 2 types of oil and a sample of *Oleum arachis* (B.P.) were tested for goitrogenic properties on 24 male rats, 7 to 8 weeks old and weighing 100 to 132 g. The basal diet consisted of sucrose 65, casein 20, groundnut oil 10 and salts 5 per cent. Water-soluble vitamins, vitamins A and D and α -tocopherol were given. The salts provided 2.8 μ g. I per rat daily. Three groups of 8 rats were fed on this diet for 20 weeks, each group being given one of the types of groundnut oil.

There was no difference between the 3 groups in weight of thyroid or in total I content of the glands, and no histological evidence that the oils had any goitrogenic property.—B. W. Simpson.

FLUX, D. S., FOLLEY, S. J. and ROWLAND, S. J. **The effect of adrenocorticotrophic hormone on the yield and composition of the milk of the cow.** *J. Endocrinol.*, 1954, **10**, 333-339. [Nat. Inst. Res. Dairying, Univ. Reading.]

Three groups of 5 cows were fed on silage and hay with concentrates, according to milk yield. The ration was constant throughout the 14-day pre-period, 10-day treatment and 14-day post-period. The adrenocorticotrophic hormone (ACTH) used had a strength of 0.78 I.U. per mg. One group of cows received injections of 100 I.U. at intervals of 48 hr. over 10 days; a second received one injection of 200 I.U. at the start of the experimental period and another 10 days later; the cows in the third group received injections of normal saline. Milk yields were recorded at each milking and at suitable times samples from individual cows were taken for analysis. Blood samples were taken before the first injection and again 24 hr. later for eosinophil counts.

Cows receiving 200 I.U. ACTH all showed a significant reduction in eosinophil counts, but the effect of 100 I.U. was variable, the range of fall being 0 to 91 per cent. At both levels single injections of ACTH caused a fall in the milk yield on the first 2 days. There was a significant correlation of +0.84 between the falls in eosinophil counts and in milk yield. Both rapidly returned to almost the original levels after treatment ceased. The treatment had only a slight effect on the composition of the milk. • Butterfat,

non-fatty solids and total protein increased, lactose decreased slightly and Na, K, chloride and N.P.N. showed no change.—W. Godden.

BROWN, G. M., BIRD, G. S., BOAG, L. M., DELAHAYE, D. J., GREEN, J. E., HATCHER, J. D. and PAGE, J. Blood volume and basal metabolic rate of Eskimos. *Metabolism*, 1954, **3**, 247-254. [Dept. Med., Fac. Med., Queen's Univ., Kingston, Ont.]

Basal metabolic rate was studied in 9 men and 7 women between 16 and 64 years old, and blood volume in 22 men aged 17 to 49 years; all were healthy Eskimos of families living by hunting and trapping.

Both B.M.R. and blood volume were high in July and declined by the end of August, the mean B.M.R. from 131.5 to 123.8 per cent. on DuBois' standard, the blood volume from 4365, S.D. \pm 580, to 3944 \pm 289 ml. per sq.m. body surface.

D. Duncan.

4687

ZUBER, G. Der Grundumsatz bei Zwergwuchs. [Basal metabolism of dwarfs.] *Helv. paediat. Acta*, 1954, **9**, 89-105. [Kinderklin., Univ. Zürich.] French, Italian and English summaries.

Basal metabolism was measured for 93 dwarfed children of ages 3 to 18 years, the term dwarf including all for whom the height age was 30 per cent. or more below the chronological age. The results were compared with those given in 7 different standard tables. In pituitary and hypothyroid dwarfism basal metabolism was uniformly reduced, but in the Turner syndrome, in progeria and in chondrodystrophy it was uniformly increased. These cases were all clinically well characterised. In forms of dwarfism which were poorly characterised clinically, e.g., primordial and dyscerebral dwarfs, dwarfism resulting from chronic internal disease or of unknown etiology, and the Cushing syndrome, there were great individual variations with normal mean values for basal metabolism. The possible causes of the different results in different forms of dwarfism are discussed. A large number of measurements on dwarfs without metabolic disturbances would be required to construct a suitable standard for basal metabolism in dwarfs.—M. B. Richards.

CLARK, L. C. (Jr.) and GARN, S. M. Relationship between ketosteroid excretion and basal oxygen consumption in children. *J. Appl. Physiol.*, 1954, **6**, 546-550. [Fels Res. Inst., Antioch Coll., Yellow Springs, Ohio.]

In boys there was a moderate correlation ($r = +0.6$) between ketosteroid excretion and basal oxygen consumption, but in girls the relation was not significant.—D. Duncan.

4689

VENKATACHALAM, P. S., SRIKANTIA, S. G. and GOPALAN, C. Basal metabolism in nutritional edema. *Metabolism*, 1954, **3**, 138-141. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor.]

An account of the 10 patients with nutritional oedema was given by Gopalan *et al.* (*Indian J. Med. Sci.*, 1952, **6**, 277). Basal metabolism (B.M.R.) was studied immediately on admission to hospital and again after disappearance of the oedema, on the average 31 days later.

B.M.R. on admission ranged from 23.3 to 34.4, mean 27.96 Cal. per sq. m. per hr., and after rehabilitation rose to 30.2 to 38.9, mean 33.4, almost normal for Indian subjects. With this rise of nearly 22 per cent. in B.M.R. the oxygen consumption per kg. cell solids rose by less than 3 per cent. The low B.M.R. during oedema was due to a reduction in the quantity of metabolising tissue.—D. Duncan.

One adult Indian male performed the muscular exercise known as "Baithaks", which consists in repeated knee-bending and stretching from squatting to the erect position. Oxygen consumption was estimated before and during exercise and recovery.

The optimum rate of work was almost identical with that found by Dickinson (*J. Physiol.*, 1929, **67**, 242) for bicycle ergometer work. An empirical formula connecting oxygen requirement and rate of work is given.—D. Duncan.

4692

TAYLOR, H. L., HENSCHER, A., MICKELSEN, O. and KEYS, A. **Some effects of acute starvation with hard work on body weight, body fluids and metabolism.** *J. Appl. Physiol.*, 1954, **6**, 613-623. [Lab. Physiol. Hyg., Univ. Minnesota, Minneapolis.]

Two sets of experiments are compared; the first, series A, was described earlier (Abst. 501, Vol. 15). In series B, 12 healthy young men fasted for 4-5 days with hard work, on 2 occasions about 6 months apart. Their total energy output in 114 hr. was between 15,000 and 16,000 Cal., compared with 9000 to 10,000 Cal. in 66 hr. in series A.

In series B the mean loss of bodyweight was 8 per cent., 65 per cent. of which was lost in the first 48 hr. In the first experiment control weight was regained by the morning of the third day of re-feeding. Plasma volume fell by 18 per cent. and thiocyanate space by 8 per cent. The gain in the first 4 days of re-feeding was mostly due to increase in body fluids; total thiocyanate space increased by 2.4 litres and represented about 40 per cent. of the weight gained. Little or no change in apparent circulating Hb occurred.

Liver function tests suggested malfunction, and one man had jaundice on the fifth day. The results are compared with others collected from the literature, on men who starved without working. Men who worked lost 2 to 2.5 times as much weight in the first day, but only 1.2 to 1.4 times as much on the fourth.—D. Duncan.

4693

HENSCHER, A., TAYLOR, H. L. and KEYS, A. **Performance capacity in acute starvation with hard work.** *J. Appl. Physiol.*, 1954, **6**, 624-633. [Lab. Physiol. Hyg., Univ. Minnesota, Minneapolis.]

In the 2 series of experiments described in the preceding abstract observations were made on pulse rate, oxygen consumption, R.Q., blood sugar, maximum oxygen intake while running, postural adjustment, and maximum performance by a Harvard fitness test.

On the second morning pulse rate during walking had risen from 130 to 145, and it remained between 140 and 151 until the end of the fast. Blood sugar dropped on the second day and subsequently rose slowly. The principal decline in work capacity occurred on the second day, with a smaller loss by the fourth. Maximum oxygen intake decreased by 7.7 per cent. between the first and fifth days, but maximum intake per unit bodyweight remained constant. Blood lactate at rest and after running increased by 198 and 31 per cent., respectively, but pyruvate was unchanged. Fat metabolism accounted for 50 per cent. of the total energy after the first period of work and for 88 per cent. on the second day, and the efficiency of grade walking declined.

The mechanisms of loss of fitness are discussed.

SULLIVAN, B. J. and MULLEN, J. T. **Effects of environmental temperature on oxygen consumption in arctic and temperate zone-mammals.** *Physiol. Zoöl.*, 1954, **27**, 21-28. [Dept. Biol., Boston Coll.]

The tests were made on 13 ground squirrels, *Citellus barrowensis*, as arctic animal, and on 10 guineapigs and 10 golden hamsters as temperate-zone animals. Oxygen consumption was measured in a constant pressure respirometer with 2 stainless steel chambers. Temperatures in the respirometer were maintained for the guineapigs at 5°, 10°, 15°, 25° and 35° C., for the hamsters at the same except 10°, and for the squirrels at 5°, 10°,

N.A. and R., October 1954

15°, 20° and 25° C. The squirrels could not survive temperatures below 5° C. unless hibernating, or above 25° C.

For the guinea-pigs and hamsters oxygen consumption showed no significant difference between 25° and 35° C., but increased significantly with fall of temperature below 25° C. The squirrels showed no significant difference at any of the temperatures. The relation to hibernation of the animals' different reactions is discussed; the arctic squirrel cannot enter into hibernation suddenly but requires a nest and conditions preparatory to sleep, from which it passes into hibernation.

ANDIK, I., BANK, J., MÓRING, I. and SZEGVÁRI, Gy. **The effect of exercise on the intake and selection of food in the rat.** *Acta physiol. hung.*, 1954, **5**, 457-461. [Inst. Pathophysiol., Med. Univ., Pécs.] Russian summary.

Ten rats received free choice of 3 diets containing one part of a standard mixture and 2 parts of starch, casein or lard. After consumption was stabilised the rats were given running exercise increasing to 8 or 9 hr. and 6 or 7 km. daily for 40 days.

A high proportion of starch was selected before the exercise period, but 8 or 10 days after exercise began starch consumption declined and more protein and fat were selected. The bulk eaten increased only slightly, but the energy value increased considerably. The choice was reversed when exercise stopped.—D. Duncan.

4701

METTA, V. C. and MITCHELL, H. H. **Determination of the metabolizable energy of organic nutrients for the rat.** *J. Nutrition*, 1954, **52**, 601-611. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Twelve adult male rats were divided at random into 3 groups of 4 rats each. A 3 × 3 latin square design in all replications was used in the plan of feeding. The 3 experimental diets contained the following, per cent.: casein 43.0, 10.0, 20.0; maize starch 10.0, 73.0, 30.0; lard 38.0, 8.0, 41.0. In addition all diets contained 0.5 per cent. wheat germ oil, 1.5 per cent. cod liver oil, 7.0 per cent. minerals and a vitamin supplement. After a

preliminary 10-day pre-period the rats were transferred to individual glass-bottom metabolism cages to permit separate and accurate collection of urine and faeces. Three 10-day periods were taken, during which each rat received successively each of the experimental diets. The daily energy requirements were calculated from the generalised equation of Brody and Procter (Abst. 2026, Vol. 2), $Q = 70.4 W^{0.734}$ for basal energy, where W is weight in kg.; to this was added 25 per cent. for activity increment. During the third collection period 2 rats became ill and were removed from the experiment. All diets, faeces and urine were analysed for gross energy and total N.

It was considered doubtful whether Rubner's factor of 7.45 Cal. per g. N balance obtained with dogs was applicable to rats. To check this, an extra experiment was made with 7 adult rats offered daily 16 g. of a diet containing 94 per cent. water-extracted lean beef with minerals, vitamins and 2 g. BaSO₄ as roughage. The new factor obtained was 6.29 ± 0.19 Cal. per g. N balance and this was employed in calculating metabolisable energy for each diet for each rat.

A multiple regression equation,

$$ME = cC + sS + fF,$$

was fitted to the 34 sets of data by the method of least squares; C, S and F are g. casein, starch and fat, on the dry basis, consumed per 10 days, ME the metabolisable energy of the diet and c, s and f the metabolisable energy per g. casein, starch and fat, respectively. These latter values as evaluated were 4.673 ± 0.089 Cal. per g. casein, 3.962 ± 0.016 Cal. per g. starch and 8.770 ± 0.065 Cal. per g. fat.—W. Godden

4702

HOHLS, H. W. **Messungen des Respirationsquotienten an ausgewachsenen und wachsenden Hühnern. [Measuring the respiratory quotient of grown and growing poultry.]** *Arch. Geflügelk.*, 1954, **18**, 144-165 [Bundesforsch. Kleintierzucht, Celle.] English summary.

The results of Diakow (Abst. 1176, Vol. 2) with grown fowls are re-analysed to show that R.Q. rose with the amount of feed (barley) digested and that the "thermal energy of feed", i.e., the difference between total oxygen consumed and carbon dioxide liberated in the fed bird and the corresponding values for the bird fasting and at rest, had an R.Q. which was independent of the amount of feed digested and was approximately 1.32.

Experiments with chicks and grown cocks in an open-circuit apparatus gave the following results. In chicks heat production varied over the day in a rhythm; when this had been sufficiently identified, short-period experiments could be corrected to whole-day values. To increase the magnitude

of the readings for oxygen consumption and CO_2 elimination, ventilation was restricted, but so that the percentage of CO_2 in the respired air did not exceed 3. Diakow's results were confirmed with 3 cocks in so far as the R.Q. of thermal energy was little affected by the amount of feed digested, but the R.Q.s were, from the diagram, roughly 0.82, 0.9 and 1.1.

Chicks were normally fed on meal and grain and their rate of weight gain and feed consumption in Cal/W^\dagger are shown in diagrams. The thermal energy of the meal, estimated separately in one experiment, was less than that of grain, so that when both were given, thermal energy varied with the proportion of meal and grain eaten. This experiment, repeated with different allowances of feed, confirmed that the loss of heat was greater with grain, that the R.Q. of the thermal energy of grain rose, with digestible energy of feed, again from a diagram, from 0.70 to about 1.0 and the R.Q. thermal energy of meal from about 0.9 to 1.3.

Further experiments are described with increasing proportion of protein in the meal to show that the thermal energy of feed increases in proportion and from this it is argued that the storage of protein by the growing animal requires expenditure of energy which is supplied by fat when necessary. With increase in feed intake, less fat is burnt, and R.Q. rises.—I. Leitch.

4703

MCDOWELL, R. E., LEE, D. H. K. and FOHRMAN, M. H. The relationship of surface area to heat tolerance in Jerseys and Sindhi-Jersey (F_1) crossbred cows. *J. Animal Sci.*, 1953, 12, 747-756. [U.S. Dept. Agric., Agric. Res. Centre, Beltsville, Md.]

In the course of crossbreeding work the surface area of 20 adult Jersey and 20 adult Sindhi \times Jersey F_1 crossbred cows was measured with a surface integrator, the construction and use of which are described. Neither the ratio of surface to bodyweight (W) nor that to $W^{0.67}$ showed any significant difference between the 2 groups. When dry cows or cows in lactation were submitted to heat tolerance tests for 6 hr. at 105°F . dry bulb and 92°F . wet bulb the rise in rectal temperature of the Jersey cows was almost twice as great as that in the crossbred cows. It would appear that differences in heat tolerance of animals such as the above are not primarily due to differences in proportional surface area, even though the presence of large dewlaps and navel folds might suggest that such a difference in surface area would be found.

The relation between area and bodyweight in the above animals and in animals of adult size reported in the literature can be expressed well enough by a straight line, and it is suggested that, when comparisons are to be made between adult

animals, there is nothing to be gained by the use of $W^{0.67}$.—W. Godden.

4704

MCDOWELL, R. E., MATTHEWS, C. A., LEE, D. H. K. and FOHRMAN, M. H. Repeatability of an experimental heat tolerance test and the influence of season. *J. Animal Sci.*, 1953, 12, 757-764. [U.S. Dept. Agric., Agric. Res. Centre, Beltsville, Md.]

Heifers and cows of a Jersey herd and of a Sindhi \times Jersey F_1 crossbred herd were submitted to heat tolerance tests at 105°F . and 34 mm. Hg vapour pressure from 6 months of age at approximately 2-month intervals except during their first lactation. Statistical examination of the results at first showed poor agreement. When the data were more closely examined the results of rectal temperature response were found to vary greatly with the time of the year. Repeatability coefficients for the rectal temperature response of heifers 8 to 22 months of age were high and satisfactory when the results were sorted into 3 seasonal groups, namely, April to July, response low, August to September and February to March, response high and October to January, response intermediate. The results are explained in terms of two conflicting responses to stress which are differentially affected by the seasonal conditions.

KIBLER, H. H. and BRODY, S. Environmental physiology with special reference to domestic animals. 19. Relative efficiency of surface evaporative, respiratory evaporative, and non-evaporative cooling in relation to heat production in Jersey, Holstein, Brown Swiss and Brahman cattle, 5° to 105°F . *Missouri Agric. Exp. Stat. Res. Bull.* No. 497, June 1952, pp. 31.

For technical details and earlier work see Absts. 2150, 5049, Vol. 21; 778, Vol. 22.

Data are presented on the effect of temperature changes between 5° and 105°F . on heat and moisture dissipation by evaporative cooling from the outer body surface and respiratory tract in lactating Jersey, Holstein, Brown Swiss and Brahman cows, and in non-lactating Brahman cows and Brown Swiss and Brahman heifers. All breeds attained maximum outer surface evaporative or "sweating" rates of about 150 g. or 87 Cal. per sq.m. per hr. but the rise to maximum levels occurred at lower temperatures in the European than in the Brahman cows. When all rates were computed to outer body surface the European breeds attained maximum respiratory evaporation rates of 50 g. or 29 Cal. per sq.m. per hr. but the Brahman did not exceed 30 g. or 17 Cal. per sq. m. per hr. The percentage of metabolic heat dis-

N.A. and R., October 1954

sipated by outer surface evaporation varied with temperature but was similar for all breeds. Their 12 per cent. greater surface area per unit weight gave Brahman an advantage over European breeds in outer surface and non-evaporative cooling over the temperature range 60° to 105° F. and a corresponding disadvantage in heat conservation below 40° F.—W. Godden.

THOMPSON, H. J., WORSTELL, D. M. and BRODY, S. **Environmental physiology and shelter engineering with special reference to domestic animals.** 23. The effect of humidity on insensible weight loss, total vaporized moisture, and surface temperature in cattle. *Missouri Agric. Exp. Stat. Res. Bull.* 531, September 1953, pp. 28.

The data were obtained during investigations reported earlier (Absts. 2000, 2498, Vol. 24). Skin or hair temperatures were recorded for 17 body areas in addition to the 6 used in earlier work (Abst. 1840, Vol. 23).

At 12° and 40° F. relative humidity did not affect vaporisation rate, but at 75°, 85° and 95° F. there was a marked depression with increasing R.H. Above 85° F. the effect was greater with Holstein than with Brown Swiss cows. At 95° and 100° F. the effect of increasing R.H. was less with Jerseys than with the larger breeds. Brahman cows appeared to dissipate a greater percentage of their total heat by evaporative cooling at high temperatures and high R.H. than did European cattle.

Great differences were found between surface temperatures at different spots on the body at the lower air temperatures. At 12° F. air temperature, the skin temperature of the Jersey hoof cleft was 30° F., that of the milkwell 85° F. In most cattle at 85° F. and above, a rise in R.H. caused an increase in skin and hair temperature. At 12° and 40° F., R.H. had no effect on skin temperature.

BADRELDIN, A. L. and GHANY, M. A. **Species and breed differences in the thermal reaction mechanism.** *J. Agric. Sci.*, 1954, **44**, 160-164. [Fac. Agric., Univ. Cairo, Giza.]

The reactions of Egyptian buffaloes and cows and Shorthorn cows to direct solar radiation were compared. Pulse rate, respiration rate and temperature were measured and skin thicknesses were compared.

Buffaloes had the lowest basal body temperature, rate of respiration and pulse, but showed the greatest reaction to solar radiation, indicated by a relatively greater increase in all 3 measurements

than in the cows. The Egyptian cows showed the least reaction. The Shorthorns were most sensitive to ambient temperature in the shade.

Skin thickness of buffaloes was double that of cows, which was the same in both breeds. In all the animals the thickness of the skin increased with age.—T. D. Bell.

Groups of 3 Southdown-sired lambs were used. One group was shorn, one clipped along the back to a width of 4 in. and one left unshorn. Over 10 test days at environmental temperatures of 90° to 96° F. body temperatures and respiration rates were significantly lower in the shorn group than in either of the other groups, between which differences were small. The results may partly explain reports of higher weight gains by shorn lambs.

LEWIS, R. C. and JOHNSON, J. D. **Observations of dairy cow activities in loose-housing.** *J. Dairy Sci.*, 1954, **37**, 269-275. [Dept. Dairy, Michigan State Coll., East Lansing.]

The behaviour of a herd of 20 Brown Swiss cows wintered in a loose-housing barn with an outside yard was observed. Climatic conditions were recorded. The animals had constant access to hay and silage for the first 2 months, after which the silage was withdrawn. When silage was available they spent on the average 5.2 hr. daily eating, 5.1 hr. loitering in the yard, 4.3 hr. loitering in the barn and 8.2 hr. resting. When there was only hay the eating time was not altered, but they spent longer loitering in the barn, less in the yard and longer resting.

Temperatures and respiration rates were significantly lower in these loose-housed cows than in Holstein cows kept in stalls. Pulse rates were higher in the Brown Swiss during the first 9 weeks and lower during the second. The differences were not correlated with differences in environmental temperature.—T. D. Bell.

GOODWIN, R. F. W. **Blood-sugar in foetal and neonatal mammals.** *Nature*, 1954, **173**, 777-778. [Dept. Animal Pathol., Milton Rd., Cambridge.]

In a study of the concentration gradient of glucose across the placenta of the guineapig it was found that the blood sugar concentration was sometimes almost the same in foetal and maternal circulations, but that plasma glucose showed a concentration gradient towards the foetus. The phenomenon was therefore studied in the horse, pig, ox, sheep, goat and rabbit.

In most species examined the foetal and immediately post-natal red blood cells contained a glucose concentration in the water phase similar to the concentration in the plasma, but the glucose within the cells gradually fell to a low level or disappeared. This occurred at different stages in different species; in the foal the change occurred before birth. The cell: plasma distribution may be different for glucose and fructose.

Figures from foetal or neonatal blood sugar estimations cannot legitimately be compared for different species or for different ages of one species without consideration of intracellular glucose concentration.—D. Duncan.

HARTMANN, A. F., MCCOY, E. E., SWARM, P. A. and NAKASATO, D. I. **Further observations on the metabolism of galactose in infants and**

children. *J. Pediat.*, 1954, **44**, 499-507. [Dept. Paediat., Sch. Med., Washington Univ., St. Louis, Mo.]

In normal full-term infants during the first month of life galactose given by mouth or by vein was well tolerated; only small amounts appeared in the blood after the standard test dose of 1.75 g. per kg. bodyweight was given by mouth, and galactose given by either route had disappeared from the blood in 3 hr. Blood glucose levels initially were unstable, as is usual in newborn infants, but within 3 hr. after galactose administration they were stabilised between 49 and 66 mg. per 100 ml. In older infants blood glucose was already stabilised and was not affected by galactose; those infants also tolerated galactose well, as did premature infants without obvious abnormality.

Impairment of galactose metabolism was found in one premature infant which showed high blood galactose and low blood glucose when fed on milk. High blood galactose was found in several infants with different infections or malnutrition and in a 12-year-old girl with cirrhosis of the liver. True idiopathic galactosaemia was seen in one infant, in which blood and spinal fluid galactose levels were almost identical.

It is confirmed that there is no renal threshold for galactose.—D. Duncan.

ALBANESE, A. A., HIGGONS, R. A., ORTO, L., BELMONT, A. and DiLALLO, R. **Effect of age on the utilization of various carbohydrates by man.** *Metabolism*, 1954, **3**, 154-159. [Nutrit. Res. Lab., St. Luke's Hosp., New York.]

Reducing sugar in the blood of 44 subjects was measured at $\frac{1}{2}$, 1, 2 and 3 hr. intervals in tolerance tests with glucose and fructose given by mouth at 1 g. per kg. bodyweight. Ages were from 5 to 89 years and utilisation of lactose was found to change only slightly with advancing years, but that of glucose became less. Comparisons of the rates of utilisation were made by tabulating the mean rise above fasting levels found after an interval of 1 hr. Tests on 7 subjects with sucrose and with invert sugar gave rates between those for glucose and fructose; for 5 subjects with lactose the rate was intermediate between those for sucrose and invert sugar.

It is concluded that for fructose the paths of availability are not affected by age in the same way as are those for glucose; fructose has thus a nutritional advantage additional to its protein-sparing action already reported (see Abst. 2304, Vol. 22).

STRUB, I. H., BEST, W. R., CONSOLAZIO, C. F. and GROSSMAN, M. I. **Utilization of intravenously injected fructose and invert sugar in normal human subjects.** *J. Clin. Nutrit.*, 1954, **2**, 32-37. [Med. Nutrit. Lab., Chicago, Ill.] Spanish summary.

Nine normal men aged 27 to 45 years received each of the following infusions for 3 hr. on separate days: 141 g. glucose, 291 g. fructose and 288 g. invert sugar. During all 3 infusions blood glucose reached a peak and then declined. In contrast, blood fructose reached a maximum and then remained fairly steady until the end of fructose or invert sugar infusion. The mean highest total blood sugar was greatest with invert sugar, 243 mg. per cent. compared with 187 and 191 mg. per cent. during glucose and fructose infusions. The mean urinary sugar loss as percentage of sugar infused was 2.12 for glucose, 6.21 for fructose and 4.96 for invert sugar.

Severe pain and cramp occurred in 6 subjects during fructose infusion, milder symptoms in 4 during invert sugar and in one during glucose infusion.—F. C. Aitken.

APPEL, W. and HANSEN, K. J. Über den Anstieg der veresterten Fettsäuren im Blut nach peroraler Zufuhr von Dextrose. [The rise of esterified fatty acids in blood after ingestion of dextrose.] *Ztschr. ges. exp. Med.*, 1953, **122**, 258-263. [Med. Klin., Univ. Kiel.]

The lipid fractions of the blood were estimated in 25 healthy subjects, fasting and 30, 60, 90 and 150 min. after ingestion of 1.5 g. glucose per kg. bodyweight. There was an increase, 30 min. after ingestion of sugar, in the esterified fatty acids of the blood of 1.68 m. equiv. methyl palmitate per litre serum. The increase, which was mainly in the neutral fats, was maintained at 60 min., the original level being regained after 90 min.

It is considered that the results represent not so much fat formation from carbohydrate as a lipolytic metabolic process accompanying glucose assimilation.—M. B. Richards.

SARETT, H. P. and SNIPPER, L. P. (with SCHNEIDER, D. L. and BARNING, C. P.). **Comparison of fructose and glucose in the diet of alloxan-diabetic rats.** *J. Nutrition*, 1954, **52**, 525-540. [Mead Johnson Res. Labs., Evansville.]

Young rats received a synthetic diet containing 64 per cent. dextrinised maize starch for 4 weeks before being injected with alloxan. Some were transferred to similar diets containing 64 per cent. glucose or fructose after 3 weeks and some after 3 months.

Weight gain and blood sugar levels were similar on glucose and on fructose diets. Food intake was slightly less on fructose and water intake considerably less, with correspondingly smaller urine volume and carbohydrate output. Only about 4.7 per cent. of the carbohydrate excreted by rats on fructose diet was fructose. There was a significant relation between blood sugar level and sugar and water excretion; when diabetic rats with the same blood sugar level were compared, those on fructose diet excreted less sugar and less urine than those on glucose.

The livers of diabetic rats on fructose diet were larger than those of diabetic rats on glucose diet or those of normal rats on dextrin diet; the latter groups were not significantly different in this respect. No histological change was found. The kidneys of diabetic rats were larger than those of controls, and contained glycogen deposits in the proximal convoluted tubules and the loops of Henle. The pancreas had fewer and smaller islets of Langerhans and fewer beta cell granules. The carcasses of diabetic rats were relatively small and contained little fat.—D. Duncan.

STURTEVANT, F. M., CALVIN, L. D. and FULLER, N. E. **The relationship among glycosuria, food intake and body weight in alloxan diabetes.** *Metabolism*, 1954, **3**, 262-267. [Div. Biol. Res., G. D. Searle and Co., Chicago, Ill.]

In a preliminary period 39 alloxan-diabetic rats were given food to appetite and glucose excretion and food intake were measured. Thereafter they were grouped and the following approximate amounts of dry food per kg. bodyweight daily were offered: 80 g. to 9, 110 g. to 11 and 130 g. to 10 rats. The 9 remaining animals were fed to appetite and they ate at the rate of 130 g.

Statistical analysis of the data indicated that 84 per cent. of the variability in urinary glucose excretion disappeared when variations in either bodyweight or food intake were allowed for. About 36 per cent. of the food eaten was excreted as glucose and, since available glucose represented 64 per cent. of the diet, slightly more than half was excreted by the kidneys. This degree of diabetes was fairly constant.—D. Harvey.

STETTEN, M. R. and STETTEN, D. (Jr.). **A study of the nature of glycogen regeneration in the intact animal.** *J. Biol. Chem.*, 1954, **207**, 331-340. [Div. Nutrit., Pub. Health Res. Inst. City of New York, Inc.]

Adult rats were maintained on stock pellets or on a synthetic diet. Each rat received a single intraperitoneal injection of 1 mM glucose uniformly labelled with ^{14}C per 100 g. bodyweight and was killed 3 to 48 hr. later. CO_2 and urine

were collected and glycogen was isolated from the tissues and purified.

Maltose obtained by treating liver glycogen with β -amylase accounted in the first few hours for most of the ^{14}C activity, but after 12 hr. there was more in the dextrin residues. In muscle glycogen the specific activity of the maltose fraction continued to exceed that in the dextrin. The glycogen molecule is thus shown not to be homogeneous; glucose residues near the periphery of the molecule are turned over more rapidly than those in more central positions.

In a rat fasted for 24 hr. to remove liver glycogen before injection of labelled glucose and killed 3 hr. after the injection, the liver glycogen was evenly labelled in maltose and dextrin fractions, but muscle glycogen was comparable to that in the fed rats.—D. Duncan.

MITCHELL, H. H. and BERT, M. H. **The determination of metabolic fecal nitrogen.** *J. Nutrition*, 1954, **52**, 483-497. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Seven experiments including 250 N balances on groups of pair-fed rats were made to estimate the biological value of whole egg protein at levels from 0.26 to 20 per cent.

The relation of faecal N to percentage of protein in air-dried diet was linear and the ratio at the lowest protein intake was not statistically different from that estimated from the regression equation of one variable on the other. Despite the results obtained by Bosshardt and Barnes with mice (Abst. 689, Vol. 16), it is concluded that direct estimation of metabolic faecal N is a valid method for studying the value of proteins.

FORSYTH, B. T., SHIPMAN, M. E. and PLOUGH, I. C. (with BOLLIER, M. and HACKELY, B.) **The variability of fecal nitrogen excretion with liquid and solid diets.** *J. Lab. Clin. Med.*, 1954, **43**, 440-444. [Med. Div., Army Med. Serv. Grad. Sch., Washington 12, D.C.]

The relation of daily N intake to daily faecal N was studied in 25 patients, from 106 stool samples over periods of 6 or 7 days, and a regression line was calculated from the data. The success of prediction of faecal N within specified limits was then found for several methods.

The methods of taking daily faecal N as 1.3 g., or as 10 per cent. of the intake, gave only from 27 to 41 per cent. accuracy of prediction within ± 0.25 g. N, and 50 to 76 per cent. accuracy within ± 0.5 g. N. The regression formula of the present series was no better in this respect than standard methods. More accurate results were obtained from an initial stool collection for prediction of future faecal N values, but this method is applicable only when N intake is constant. It is concluded that for accurate N balance calculation it is essential to analyse the stools.—M. B. Richards.

CRISPELL, K. R., PARSON, W. and HARDEN, G. (with BRENT, S.). **The relation of dietary protein consumption to N-15 excretion in normal subjects and in Cushing's syndrome utilizing N-15 glycine orally and intravenously.** *J. Clin. Invest.*, 1954, **33**, 342-346. [Dept. Int. Med., Sch. Med., Univ. Virginia, Charlottesville.]

Three diets were used: normal, high- and low-protein, supplying, respectively, 1 g., 1.6 g. and 0.4 g. protein per kg. bodyweight. Labelled glycine was given at breakfast time when the subjects had been on the diets for a week and were, with a few exceptions, in N equilibrium. Some subjects were given breakfast at breakfast time, for others breakfast was postponed until the evening; the other meals of the day were eaten at the usual times. In healthy subjects given labelled glycine by mouth or by vein the proportion of ^{15}N excreted in the urine in 24 hr. was greater on a high-protein diet and smaller on a low-protein diet than on a normal protein diet. The percentages were somewhat lower when the labelled glycine was given by vein than when given by mouth. The eating of food at the time of glycine administration did not affect the results.

A patient with Cushing's syndrome excreted equally high proportions of ^{15}N on normal- and high-protein diets.

Possible explanations of these results are discussed.—F. C. Aitken.

4741

STANIER, M. W. and HOLMES, E. G. **Malnutrition in African adults. 1. Serum proteins, cholinesterase, and protein-bound lipid.**

2. Protein storage. *Brit. J. Nutrition*, 1954, **8**, 155-164; 173-193. [Dept. Physiol., Makerere Coll., Kampala, Uganda.]

1. The patients were 14 African men suffering from malnutrition with or without liver damage; in hospital they were given a high-protein diet and treated for hookworm with trichloroethylene.

In every patient serum albumin was initially low and globulin high. During recovery the most striking change was the rise in the red cell count; albumin also increased, but not parallel to the red cell count. Globulin sometimes fell, but in 5 patients was almost the same on discharge as initially. The main change in total globulin was in a fraction measured chemically as β -globulin but behaving electrophoretically as γ -globulin; this component was increased in malnutrition.

Serum pseudo-cholinesterase was low initially and rose during treatment, and was significantly correlated with albumin ($r = +0.74$).

Less lipid was carried in the serum lipoproteins than in those of normal subjects.

2. Nitrogen balances were estimated in several of the subjects, maintained on diets high in energy and in protein. N was retained steadily at rates of up to 10 g. daily for many months, but the observed changes in bodyweight were not related to this retention. The reasons for the discrepancy are discussed. N absorption appeared to be poorer than in healthy controls, N loss in the faeces being significantly greater. In 5 subjects cortisone decreased N retention.—D. Duncan.

4742

KELLEY, L. and OHLSON, M. A. **Experimental variables in predicting protein minima for rats.** *J. Nutrition*, 1954, **52**, 325-335. [Dept. Foods Nutrit., Michigan State Coll., East Lansing.]

A series of experiments of cross-over Latin square design was made with rats. The diets used contained none or up to 10 per cent. of dried egg and 4 or 12 per cent. lard. Weight change, energy intake, N intake and N balance were obtained for each rat over 7-day balance periods.

Period effects which may reflect changes in protein stores during the experiments were noted in some. Regression analyses, used to obtain minimum N requirement, showed that the best prediction of weight change was obtainable from N balance, and that it is dependent much more on N than on energy intake, at least under conditions of negative N balance. A comparison between results with rats on low- and high-energy diets suggested that the calories added as fat did not affect the N intake needed for weight maintenance but led to a greater positive N balance. N utilisation was almost as efficient in the area above maintenance as in that below maintenance.

I. McDonald.

4743

PIKE, R. L., SUDER, H. B. and ROSS, M. L. **The influence of protein and energy intakes upon nitrogen retention in the pregnant rat.** *J. Nutrition*, 1954, **52**, 297-309. [Dept. Foods Nutrit., Pennsylvania State Univ., State College.]

Groups of pregnant rats were fed to appetite on 3 rations, low in protein (17 per cent.), in energy or in both. Little difference was noted in maternal weight gain, litter size or foetal weight. Mean N intake and N retention were greatest with the 25 per cent. protein diet, but the highest percentage N retention was with the low-protein, high-energy diet. N retention was in all groups greatest during the third week of pregnancy. On the low-protein, low-energy diet, N retention during the second week of pregnancy appeared to be limited by the energy intake, but during the third week by the protein intake.

It is suggested that N retention, rather than birthweight of the young, be considered the criterion of adequacy of a diet for reproduction in the rat.

DEBAUN, R. M. and CONNORS, W. M. **Relationship between *in vitro* enzymatic digestibility and *in vivo* protein evaluation of powdered whey.** *J. Agric. Food Chem.*, 1954, **2**, 524-526. [Nat. Dairy Res. Labs., Oakdale, N.Y.]

A positive correlation was found between the amount of lysine liberated by digestion with trypsin and the biological value of the proteins of different dried whey powders. No such correlation was found if the digestion *in vitro* was with pepsin followed by trypsin and chymotrypsin, nor was the N.P.N. concentration or the formol titration of the digest a satisfactory substitute for lysine estimation. Roller-dried whey powders, compared with spray-dried powders, showed little loss of arginine or tryptophan after tryptic digestion, but considerable loss of histidine and lysine; on the other hand, histidine and lysine were relatively stable to storage for 6 months at 40° F., but there was loss of arginine.—C. Warner.

4745

LÓZSA, A. and KOLLER, K. **Estimation of the biological value of rice proteins.** *Acta physiol. hung.*, 1954, **5**, 477-487. [Inst. Pub. Health, Med. Univ., Szeged.] Russian summary.

Dogs were given a protein-free diet for 5 to 6 weeks, until serum albumin had fallen to about 30 per cent. of the total plasma protein. Pairs of dogs then received supplements of 1.5 g. protein per kg. bodyweight daily from casein, whole rice (oryzenin plus globulin plus prolamin), prolamin-free rice (oryzenin plus globulin) or oryzenin.

N.A. and R., October 1954

With casein as a standard, the relative biological values of the proteins as calculated from the mean time of serum albumin regeneration were whole rice protein 81.4, oryzenin 85.4, globulin 85.4 and prolamin 35 per cent. Hungarian species of rice are considered equal in quality to foreign species.

Dogs on protein-free diets developed fatty livers, but all the proteins were protective.—D. Duncan.

ESH, G. C. and BASU, U. P. **Studies on the nutritive value of enzymatic protein digests. 2. Digestion of casein and groundnut cake with papain and *Aspergillus oryzae*.** *Indian J. Physiol. Allied Sci.*, 1954, **8**, 18–25. [Bengal Immunity Res. Inst., Calcutta 16.]

The growth response when young adult rats received protein hydrolysates after 12 days on a nitrogen-free diet was measured. Casein, whether digested by papain or an *Aspergillus oryzae* preparation, supported good growth. Groundnut cake digested by papain supported moderate growth, which could be improved by adding choline, cystine or methionine; lysine or threonine with methionine gave no extra effect, but the 3 amino-acids together formed a supplement which permitted the groundnut digest to support as good growth as the casein digests. Animals fed on groundnut cake digested by the *Aspergillus* preparation continued to lose weight, which suggested the presence of toxic substances in the digest.

SCHNEIDER, B. H. and MILLER, D. F. **The biological value of Alaska pea proteins.** *J. Nutrition*, 1954, **52**, 581–590. [Dept. Animal Husb., State Coll. Washington, Pullman.]

Measured with growing rats and at 9 per cent. protein level average biological values for raw and cooked Alaska pea proteins were 60.6 and 61.7 per cent., respectively. Addition of 0.3 per cent. methionine to the peas increased these values to 77.6 and 76.9 per cent. With adult rats and at 6 per cent. protein level average egg replacement values were 78.0 and 72.8 per cent., and with the

same addition of methionine 89.3 and 88.3 per cent., for the pea proteins in raw and cooked forms, respectively.—D. Harvey.

FINK, H., SCHLIE, I. and HEROLD, E. **Über die Eiweissqualität einzelliger Grünalgen und ihre Beziehung zur alimentären Lebernekrose der Ratte. Ein Beitrag zur mikrobiellen Eiweiss- und Fettsynthese. 11. [Protein quality of unicellular green algae and its relation to alimentary liver necrosis in rats. Contribution to synthesis of protein and fat by micro-organisms. 11.]** *Naturwissenschaften*, 1954, **41**, 169. [Int. Gärungswiss., Univ. Cologne.]

Dried material of the unicellular alga *Scenedesmus obliquus* was tested for digestibility and protein quality as measured by the growth of rats. The digestibility *in vivo* was only 60.8 per cent., but the growth curves were as good as those obtained with milk protein, a result not hitherto obtained with any protein of higher fungi, yeasts, moulds or bacteria. In an experiment of 120 days' duration on 20 rats none died, and there was no liver necrosis such as frequently occurred with other fungi or moulds. Apparently the algal material contains adequate amounts of protective substances; tests for their differentiation are not yet completed.—M. B. Richards.

1. A Cheviot ewe maintained during pregnancy on a high plane and another on a low plane of nutrition had their N balances estimated about 6 weeks before lambing on their basal diets, the same supplemented with 50 g. casein, and again on the basal diet. The sheep on the high-plane diet retained 49 per cent. of the supplementary N administered as casein, but the one on the low-plane diet retained only 15 per cent., despite the fact that this animal was in negative N balance.

Similar pregnant ewes 5 or 6 weeks before lambing or non-pregnant ewes, with rumen and duodenal fistulae and all on the low-plane diet, received 50 g. casein by drip into the rumen or duodenum and the effect on their N balance was measured. In all the apparent retention of N of casein supplements was greater with duodenal than with ruminal administration. The extensive conversion of casein to ammonia in the rumen with absorption of NH_3 into the bloodstream was confirmed (*cf.* Abst. 2364, Vol. 22). The course of dissolution in the rumen of casein in the form of tough lumps was followed by the use of stains. A comparison of the N retention of casein given as commercial casein, tough lumps or ground lumps showed the highest value with the ground material; the concentration of ammonia in the rumen liquor was greater with the commercial casein than when the ground material was the supplement. It is concluded that the tendency to value proteins for ruminants in terms of their digestibility is liable to be misleading.

2. When two types of herringmeal and two of casein were given as supplements to Cheviot ewes the concentration of ammonia in the rumen liquor was higher and the retention of supplemental N was less with the latter than with the former.

Growth experiments are reported with Cheviot lambs aged 7 months, on a high-plane basal diet, and with Blackface lambs aged 9 months, on a low-plane diet. The animals were individually caged and fed. Some animals received herringmeal, others casein or maize starch in roughly

isocaloric amounts as supplements. In the high-plane animals there was no significant difference in weight increase between the groups during 91 days or in carcase grading. In the low-plane animals the herringmeals gave much greater liveweight increases and the animals had more bloom. The animals receiving casein or starch put on relatively little weight, although they had greater deposits of fat than the herringmeal animals. None of the meat samples had any taint from the herringmeal. Formaldehyde had been used to preserve one lot of herringmeal, but this did no harm.

3. Cheviot sheep with ruminal fistulae, fed on basal diets of hay or hay and meals, received different supplementary proteins and the concentration of ammonia in the rumen liquor was measured. Ammonia production was great from groundnut meal and slight from maize products. The extent of ammonia production from a given protein concentrate decreased as the amount of starch or cereal meal was increased. Groundnut meal, herringmeal, casein and maize products were the supplements tested.—W. Godden.

FEKETE, L. and KÖRÖPÁČY, I. Beobachtung des Dynamismus der Eiweiss-synthese bei Serum-regenerationsuntersuchungen. [Observation on the dynamics of protein synthesis in serum regeneration experiments.] *Acta physiol. hung.*, 1954, **5**, 469-476. [Inst. Ernährungswiss., Budapest.] Russian summary.

Data are given for synthesis of total serum protein and albumin in regeneration experiments on adult dogs. The animals, previously on full diet, were given a protein-free diet supplying 80 Cal. per kg. bodyweight for 6 weeks, followed by a diet with ample protein as casein, whole milk powder, whole egg or meat for 8 weeks, then the protein-free diet for 6 more weeks and finally the ample diet for 10 weeks. Serum protein fractions were estimated by a nephelometric method in samples taken weekly.

The graph for total protein and albumin values in the different periods show characteristic changes, similar for all 4 foodstuffs tested. Neither in the protein-free nor in the protein-rich period was there a steady change in the values; a succession of peaks and depressions in the curves led gradually to a lower or higher level. Protein withdrawal was seldom followed by an immediate and lasting decrease in serum protein, and ingestion of protein did not lead to an immediate increase.

CRAFTS, R. C. The value of a high protein diet in the prevention of anemia in hypophysectomized adult female rats by means of thyroxine and androgen therapy. *Endocrinology*, 1954, **54**, 542-549. [Dept. Anat., Coll. Med., Univ. Cincinnati, Ohio.]

Hypophysectomized rats which received daily subcutaneous injections of 0.005 mg. thyroxine and 1.0 mg. testosterone propionate showed no anaemia. On the 50th day of treatment the red cell count was 8.83 million per c. mm., the haematocrit 43.2 per cent. and Hb 15.6 g. per 100 ml. Hypophysectomized rats without these injections showed the usual anaemia, the corresponding data for them being 7.23, 35.5 and 12.6; for untreated normal controls the values were 8.63, 44.4 and 15.7, respectively. Treatment with a high-protein diet, 62.5 per cent., in addition to the thyroxine and testosterone propionate induced a rise in the red cell count to 9.68 million per c. mm., in the haematocrit to 47.6 per cent. and in Hb to 17.0 g. per 100 ml.—M. B. Richards.

ROTH, J. S. Incorporation of N¹⁵ into protein and P³² into nucleic acid of the thermally injured rat. *Amer. J. Physiol.*, 1954, **176**, 471-474. [William Goldman Isotope Lab., Hahnemann Med. Coll., Philadelphia, Pa.]

Adult rats with burns of moderate severity excreted on the second and third days 25 per cent. more N than unburned rats. The increase was mostly in urea N; ammonia N excretion fell and faecal N rose only slightly. More ¹⁵N injected as glycine was incorporated in 24 hr. into liver, spleen and intestine and less into kidney by burned rats than by controls. Formation of ammonia from glycine ¹⁵N was 42 per cent. less, and after 72 hr. formation of labelled urea was 121 per cent. greater, though in the first day it was less.

Incorporation of ³²P into liver and intestinal nucleic acids was depressed after 24 hr., but in kidney and spleen it was increased.—D. Duncan.

DEMLING, L. Die Proteinkomponenten der geschädigten Leber. [The protein components of diseased liver.] *Gastroenterologia*, 1954, **81**, 129-152. [Med. Poliklin., Univ. Würzburg.] English and French summaries.

For preliminary accounts see Abst. 61 and Title 2557, Vol. 22.

Vol. 24, No. 4

Liver homogenates were centrifuged for 30 min. at 1200 g and the cytoplasmic fraction was subjected to paper electrophoresis by the method of Grassmann and Hannig (Abst. 42, Vol. 21; *Arch. exp. Pathol. Pharmacol.*, in the press); the technique is discussed in detail.

The experimental animals, 200 in all, were young adult female rats weighing from 130 to 170 g. Nine were fed for some weeks on a diet of wheat flour, carrots and lard, low in protein and B vitamins. In others the liver was damaged in other ways, namely, by a single injection of carbon tetrachloride, ligation of the bile duct, treatment with hepatotoxic serum, whole-body exposure to X-rays, or inoculation with Walker carcinoma.

Fifty-four human livers were also studied *post mortem*.

Normal rat liver cell protein consisted of albumin 4.8, α -globulin 20.4, β -globulin 44.8 and γ -globulin 30 per cent. In rats on the defective diet α -globulin showed at first a slow steady rise and then a fall, and after about 7 weeks β -globulin fell and γ -globulin rose. Liver damage due to the other procedures was also associated with a fall of β -globulin and a rise of γ -globulin, so that the β : γ ratio was reversed.

β -Globulin was also the most prominent component in the 2 normal human livers studied; albumin was higher than in the rat. The pathological specimens showed the same reversal of the β : γ ratio, whether death was due to liver disease or not.

In the serum of the rats α - and γ -globulin generally behaved in the same way as the liver cell protein fractions, but β -globulin in the reverse way [details not reproduced].

The results are discussed with reference to the role of the liver in protein synthesis.—W. M. Deans.

WACHSTEIN, M. and MEISEL, E. Relation of dietary protein levels to pancreatic damage in the rat. *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 314-317. [Dept. Pathol., St. Catherine's Hosp., Brooklyn, N.Y.]

Sixty young rats received a protein-free basal diet of percentage composition maize starch 70, vegetable oil 10, cellulose 15, cod liver oil 1 and salt mixture 4, with added vitamins. Other groups of 15 received this diet with supplements of 2, 4 and 7.5 per cent. casein and 1 per cent. *DL*-methionine, respectively. Rats were killed at intervals between the fifth and seventy-fifth days for histological study of the pancreas; those which died were not used.

With the protein-deficient diet there was slow atrophy of acinar cells with loss of zymogen granules, subsequent dissociation of the acini and finally focal proliferation of connective tissue.

The islet tissue was not affected. The 2 per cent. protein supplement did not prevent these changes, but 4 per cent. casein or 1 per cent. methionine gave some protection and with 7.5 per cent. protein the pancreas was almost normal.—D. Duncan.

BLOCK, R. J. and ZWEIG, G. **Studies on bovine whey proteins. 2. Removal of iron from the ferric derivatives of the whey proteins.** *Arch. Biochem. Biophys.*, 1954, **48**, 386-394. [Biochem. Res. Labs., Special Products Div., The Borden Company, Yonkers, N.Y.]

For part 1 see Abst. 2042, Vol. 24.

Three methods were effective in removing Fe from ferrilactin. Reduction with SO_2 gave a denatured mixture of whey proteins readily digestible *in vitro* by pepsin or trypsin but, when compared with heat-coagulated whey proteins, of low nutritive value for growth of young rats unless supplemented with methionine, tryptophan and arginine. Treatment with sodium dithionite gave 2 fractions, one less extensively degraded than the proteins obtained by the first treatment and another resembling β -lactoglobulin in ionic mobility and coagulability by heat. Dialysis against HCl solution, pH 2, gave a mixture mainly of α -lactalbumin and β -lactoglobulin.—D. Harvey.

4761

HARKNESS, R. D., MARKO, A. M., MUIR, H. M. and NEUBERGER, A. **The metabolism of collagen and other proteins of the skin of rabbits.** *Biochem. J.*, 1954, **56**, 558-569. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

The proteins of the skin of growing rabbits were fractionated as follows: a mixture of cellular proteins, plasma proteins and a small amount of a collagenous protein, here named alkali-soluble collagen, soluble in disodium phosphate; acid-soluble collagen insoluble in the phosphate but soluble in a citrate buffer at pH 3.8; an insoluble collagen converted to gelatine by autoclaving; and an insoluble residue. The amounts of hydroxyproline, glycine and tyrosine in the 3 collagen fractions were similar but not identical. Intraperitoneal injection of [^{14}C]-glycine resulted in widely differing radio-activity of similar fractions in different rabbits, though the ratios of radio-activity for different fractions from the same rabbit were fairly regular. Intravenous or oral administration gave much less variable results.

Glycine was isolated from the skin and the plasma proteins from 0.3 to 7 days after labelled glycine was given by mouth, and its radio-activity was measured. The phosphate-soluble protein and the insoluble residue gave activity/time curves similar to those of plasma protein. The curve for insoluble collagen was low and almost flat, that

for acid-soluble collagen showed a slow rise, and that for alkali-soluble collagen showed a marked rise 24 hr. after the dose, then a rapid fall to low values. It is concluded that the alkali-soluble collagen is a true precursor of the other collagen fractions and that the acid-soluble fraction is not a necessary intermediate of all the insoluble collagen of the skin.—C. Warner.

AGAR, W. T., HIRD, F. J. R. and SIDHU, G. S. **The uptake of amino acids by the intestine.** *Biochem. biophys. Acta*, 1954, **14**, 80-84. [Dept. Physiol., Univ. Melbourne, Victoria.] French and German summaries.

Segments of isolated rat intestine took up L-histidine from a glucose-bicarbonate buffer solution until the concentration in the wall of the intestine was up to 3 times that in the external solution; equilibrium between segments and surrounding fluid could be reached from either direction. On the other hand, D-histidine was taken up only to a small extent and was not concentrated in the intestine. In the presence of cyanide or dinitrophenol, L-histidine behaved like D-histidine.

It is suggested that amino-acids are transported across the intestinal wall against a concentration gradient by uptake from the lumen as shown in this paper, distribution inside the epithelial cells and then diffusion down a concentration gradient into the bloodstream.—C. Warner.

4765

SHISHOVA, O. A. **Vliyanie fosfornykh soedinenii na vsasyvanie aminokislot. [Influence of phosphorus compounds on amino-acid absorption.]** *Vop. Pitan.*, 1954, **13**, No. 3, 16-18. [Inst. Pitan., Akad. Med. Nauk SSSR, Moscow.]

Male white rats of about 200 g. were used throughout the experiments. Estimations on tissues showed that the inorganic phosphorus content of intestine was high. Amino-acid absorp-

tion was studied in closed loops of small intestine and was most rapid when inorganic phosphate plus adenosinetriphosphate was added to the acid mixture.—D. W. Taylor.

4766

WU, C. **Metabolism of free amino acids in fasted and zein-fed rats.** *J. Biol. Chem.*, 1954, **207**, 775–786. [Sect. Biochem., Mayo Clin., Rochester, Minn.]

When rats were fasted for up to 9 days the total α -amino-N protein and plasma, liver and muscle contained less than in controls fed on casein. The free amino-acids of these tissues were separated by paper chromatography and estimated colorimetrically after elution; alanine, glutamic acid, glutamine, glycine, serine and threonine decreased and taurine, valine and leucine plus isoleucine increased considerably in concentration. Urinary excretion of free amino-acids decreased, but excretion of taurine increased.

When zein was given, the decreases in the concentrations of free amino-acids in the tissues, which again accompanied decrease in protein, were less marked except for decrease of lysine. Urinary excretion of free amino-acids again decreased considerably, though large amounts of bound amino-acids were still excreted.—C. Warner.

4767

ALMQUIST, H. J. **Proportional requirements of amino-acids.** *Arch. Biochem. Biophys.*, 1954, **48**, 482–483. [The Grange Company, Modesto, Calif.]

The author re-examined some of his published work (Abst. 4713, Vol. 17) and concluded that tryptophan, methionine, lysine and arginine were required in the same relative proportions in diets with the same protein content but giving a wide range of growth rates for chickens.—C. Warner.

4768

WILLIAMS, H. H., CURTIN, L. V., ABRAHAM, J., LOOSLI, J. K. and MAYNARD, L. A. **Estimation of growth requirements for amino acids by assay of the carcass.** *J. Biol. Chem.*, 1954, **208**, 277–286. [Dept. Biochem., Cornell Univ., Ithaca, N.Y.]

Rats, chicks and pigs were killed at different stages of growth and 12 or 14 amino-acids were estimated in the carcasses. The patterns of amino-acid composition were similar for all, and so were the estimated amino-acid requirements. Most differences between the 2 sets of figures could be explained as due to the use of amino-acids of the food for purposes other than protein formation, e.g., of methionine as a methyl donor or tryptophan for nicotinic acid formation, or to possible inadequacies of the nutritional experiments. Carcase

Vol. 24, No. 4

analysis is recommended as a method for estimating the requirement for growth of all or most of the essential amino-acids.—C. Warner.

WOOD, J. L. and COOLEY, S. L. **Substitution of α -keto acids for five amino acids essential for growth of the rat.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 409–411. [Dept. Biochem., Univ. Tennessee, Memphis.]

When young rats were fed on a diet with the 10 essential amino-acids and glutamic acid as N source, growth was slow. When some of the amino-acids were replaced by the corresponding α -ketone bodies, with an equivalent amount of N as glycine, growth ceased, probably because the rats failed to eat. When extra vitamin B₁ and aspartic acid were added and the diet was kept dry, it was eaten and the amino-acids leucine, isoleucine, valine, phenylalanine and methionine could be replaced by their ketone bodies with as good growth as on the basal diet.—C. Warner.

BEARN, A. G. and KUNKEL, H. G. **Abnormalities of copper metabolism in Wilson's disease and their relationship to the aminoaciduria.**

STEIN, W. H., BEARN, A. G. and MOORE, S. **The amino acid content of the blood and urine in Wilson's disease.** *J. Clin. Invest.*, 1954, **33**, 400-409; 410-419. [Labs., Rockefeller Inst. Med. Res., New York.]

Serum and urinary Cu, serum Cu enzyme or ceruloplasmin and α -amino-N in urine were estimated in 17 patients with Wilson's disease, 23 with cirrhosis of the liver and 12 normal subjects. Low values of Cu in serum were found in all except one patient with Wilson's disease; in liver cirrhosis values were normal or above. All patients with Wilson's disease had low ceruloplasmin and high urinary Cu; high ceruloplasmin and slightly increased urinary Cu values were found in liver cirrhosis. Amino-acids occurred in urine in 16 of the 17 patients with Wilson's disease, not at all in 35 unaffected siblings and not in any of the patients with liver cirrhosis. In Wilson's disease increase in amino-acid excretion due to increased protein intake or to cortisone administration was accompanied by a parallel increase in urinary Cu excretion.

Amino-acid distribution in 24-hr. specimens of urine was investigated by chromatography in 6 patients with Wilson's disease. Increases above normal were greatest for threonine and cystine, followed by serine, glycine, asparagine, valine, tyrosine and lysine, followed by histidine, ornithine and phenylalanine. Conjugated amino-acids were excreted in amounts greater than normal. A study of the plasma in 2 patients showed almost normal amino-acid distribution. The amino-acid composition of fasting samples of urine was studied in 2 normal subjects and 2 with Wilson's disease; only in patients with Wilson's disease was the distribution different from that of 24-hr. specimens. Giving a protein meal to a normal subject and one with Wilson's disease resulted in approximately similar rises in plasma amino-acid levels. There was no appreciable change in urinary amino-acids in the normal subject and large increases in most urinary amino-acids in the patient with Wilson's disease.

It is concluded that the loss of amino-acids in urine in Wilson's disease is the result of a renal lesion.—F. C. Aitken.

ULRICH, J. A. (with SCHROPP, M. and MARTIN, E. J.) **Urinary excretion of amino acids by**

human subjects on unrestricted diets. *Proc. Staff Meetings Mayo Clin.*, 1954, **29**, 210-214. [Sect. Biochem.]

Free and total amino-acids were estimated in 24-hr. samples of urine from 14 women aged 20 to 40 and 12 men aged 20 to 60 years, eating their usual diets. Values are tabulated for 14 amino-acids.

Men excreted more arginine, aspartic acid, histidine, leucine, methionine, phenylalanine, threonine, tryptophan and tyrosine, but less proline, than women. One man had a significantly high output of lysine, the only significant departure from the mean levels of excretion.—D. Duncan.

COLE, A. S. and SCOTT, P. P. **Tissue changes in the adult tryptophan-deficient rat.** *Brit. J. Nutrition*, 1954, **8**, 125-138. [Dept. Physiol., Univ. Bristol.]

Adult rats were rendered tryptophan-deficient by feeding them on an acid-hydrolysed casein diet for more than 100 days, and were compared with normal and pair-fed controls on an unhydrolysed casein diet and others fed on the hydrolysed casein supplemented with 0.2 or 0.01 per cent. tryptophan.

The deficient rats showed emaciation, anorexia, staring coats, hypochromic anaemia, permanent dioestrus, staining of the wrists, paws and nose with reddish material presumed to be a porphyrin, and nervous signs including lethargy, atonia and hyperexcitability. The liver showed chemical, histological and cytological evidence of loss of substance, notably ribonucleoprotein; mitochondria and other cytoplasmic granules were reduced in number and distorted. Chemical and histological examination for fat and glycogen gave fairly normal results, compared with low figures for the pair-fed controls. Epithelial and secretory tissues showed a reduction of cytoplasm, voluntary muscle fibres were reduced in diameter, and testes showed degenerative changes. Most of these effects appeared to be specifically due to the deficiency of tryptophan. Inclusion of a small, inadequate amount of tryptophan in the diet did not exert a protective effect on any individual tissue.—C. Warner.

MACHLIN, L. J. **Methionine metabolism in the laying hen. 1. Effect of change in the dietary**

N.A. and R., October 1954

protein or tryptophan level on deposition of S^{35} in the egg. *Poultry Sci.*, 1954, **33**, 201-205. [Bur. Animal Indust., U.S. Dept. Agric., Beltsville, Md.]

Four hens fed on a ration containing 19 per cent. protein and made of soya bean meal 24, fishmeal 5, alfalfa meal 5, bonemeal 3, minerals 3, butyl fermentation solubles 0.5, vitamins A and D oil and yellow maize meal to 100, were given an injection of 0.8 mg. DL-methionine labelled with ^{35}S . In the next 10 days 27 per cent. of the ^{35}S was recovered in the excreta and 31 per cent. in the eggs. The yolks contained about twice as much as the whites. Maximum ^{35}S activity was found in the whites laid 3 days and the yolks laid 6 days after injection.

After 11 days 2 hens were transferred to a ration containing 9 per cent. crude protein; for the next 2 weeks the eggs from these birds had higher ^{35}S contents than eggs from the birds given the high-protein diet. This is evidence that the amino-acid intake was inadequate for egg production, and that tissue reserves had been called on; and it is suggested that the technique might be used to study the amino-acid requirements of the laying hen.

Similar results were obtained with rations containing different levels of tryptophan.

SHERWOOD, F. W., WELDON, V. and PETERSON, W. J. Effect of cooking and of methionine supplementation on the growth-promoting property of cowpea (*Vigna sinensis*) protein. *J. Nutrition*, 1954, **52**, 199-208. [Nutrit. Sect., Dept. Animal Husb., N. Carolina Agric. Exp. Stat., Raleigh.]

Nine samples of cowpeas grown in 1947 were compared. Part of the sample was ground and used raw and part was soaked overnight, cooked and dried before being ground. The peas provided 12 per cent. crude protein in a diet containing hydrogenated vegetable fat 9, cod liver oil 1, $CaCO_3$ 1, NaCl 0.5 and starch to 100 parts, with a vitamin supplement. Besides these 18 diets, 6 containing raw cowpeas were supplemented with 0.3 per cent. methionine. The diets were given to appetite for 21 days to rats in a 5×5 balanced lattice experiment.

The differences in growth between rats on the unsupplemented raw cowpea diets were not significant. Cooking significantly improved the value of some samples but not of others. The methionine supplement gave significantly better growth than either raw or cooked cowpeas without methionine. Lack of available methionine is considered to limit the growth of young rats given cowpeas as the sole source of protein.—D. Duncan.

EDWARDS, L. J. Utilization of topically applied methionine by the guinea pig. *Nature*, 1954, **173**, 1042-1043. [Beecham Research Laboratories, Ltd., Brockham Park, Betchworth, Surrey.]

A solution of methionine- ^{35}S was injected intramuscularly, given by mouth or applied locally to shaved skin, and hair from treated guineapigs was clipped at intervals for estimation of its radioactivity.

After intramuscular injection 3 to 5 per cent. of the dose appeared in the hair, the peak of activity occurring after 2 weeks and some activity still remaining after 2 months. About 2 per cent. of the dose given by mouth and 1 per cent. of that applied locally appeared in the hair. Most of the activity of the hair was in the cystine fraction.

MILLER, L. L. and BALE, W. F. The metabolic conversion of the carbon chain of lysine- $6-C^{14}$ to glutamic acid, aspartic acid and arginine. *Arch. Biochem. Biophys.*, 1954, **48**, 361-369. [Dept. Radiation Biol., Sch. Med., Univ. Rochester, N.Y.]

When dogs received DL-lysine-6-¹⁴C by mouth, radio-activity was found in the lysine, glutamic acid, aspartic acid and arginine of plasma and liver. About three-quarters of the activity of the glutamic acid came from the γ -carboxyl C atom, the remainder from the α -carboxyl atom. It is suggested that lysine may be converted to glutamic acid in part directly via ketoglutarate, and in part indirectly via acetate.

The activity of arginine was evenly distributed between the ornithine and guanidine moieties, none coming from the carboxyl group. It was thought more likely that arginine and glutamic acid had a common precursor, such as ketoglutarate, than that arginine was formed from glutamic acid.—C. Warner.

ROSENBERG, H. R., ROHDENBURG, E. L. and BALDINI, J. T. **The fortification of bread with lysine. 3. Supplementation with essential amino acids.** *Arch. Biochem. Biophys.*, 1954, **49**, 263-267. [Stine Lab., Grasselli Chem. Dept., E.I. du Pont de Nemours and Co., Inc., Newark, Del.]

For earlier work see Abst. 185, Vol. 22 and 607, Vol. 23. The technique and basal diets were as described in the second paper.

No benefit resulted from supplementing the basal bread diets containing 0.2 or 0.4 per cent. added lysine with 0.1 per cent. DL-methionine, or 0.2 or 0.4 per cent. L-valine, or 0.1 per cent. L-threonine, or all these amino-acids together. It is concluded that for growth of rats the only amino-acid deficient in commercial white bread is lysine.—D. Duncan.

ROTHSTEIN, M. and MILLER, L. L. **Loss of the α amino group in lysine metabolism to form pipercolic acid.** *J. Amer. Chem. Soc.*, 1954, **76**, 1459. [Dept. Radiation Biol., Sch. Med. Dent., Univ. Rochester, N.Y.]

With the technique described earlier (Abst. 737, Vol. 24) it was shown that when DL-lysine- ϵ -¹⁵N HCl was injected intraperitoneally into a fasted rat pure pipercolic acid containing ¹⁵N could be isolated from the urine. This supports the view expressed previously that the formation of pipercolic acid is a major and primary step in lysine metabolism.—W. Godden.

COXON, V. and KOLB, F. O. **The use of oral choline in cystinuria.** *Metabolism*, 1954, **3**, 255-261. [Dept. Med., Harvard Med. Sch., Boston, Mass.]

Urinary cystine was estimated by conversion to cysteine and use of the nitroprusside reaction, the procedure described being based on that of Krishnaswamy (Title 16, Vol. 12).

Administration of 3 or 8 g. choline chloride daily to 3 cystinuric subjects, of whom 2 were also receiving sodium citrate, did not affect excretion of cystine in the urine. This suggests that the conversion of methionine to cystine in the cystinuric subject is not influenced by the availability of labile methyl groups.

In conclusion, theories of the etiology of the condition are discussed.—W. M. Deans.

GIANETTO, R. and BOUTHILLIER, L. P. **The metabolism of DL-hydroxyproline-2-C¹⁴ in the rat.** *Canad. J. Biochem. Physiol.*, 1954, **32**, 154-160. [Dept. Biochem., Univ. Montreal, Que.]

Synthesis of DL-hydroxyproline-2-¹⁴C is described. Doses of 65 and 100 mg. were given by intraperitoneal injection to one and two rats, respectively. The rats were fasted for 15 hr. before the injection and CO₂ and urine were collected for 4 hr. afterwards; the rats were then killed and the carcasses analysed.

¹⁴C excretion in respired CO₂ was about 12 per cent. of that injected, and in urine 20, 25 and 28 per cent. In rats 2 and 3, 65 and 63 per cent. of the ¹⁴C in the urine was in excreted DL-hydroxyproline. Of the amino-acids isolated from tissue proteins glutamic acid had the highest specific activity, then aspartic acid and hydroxyproline, but proline had very little activity.

A pathway is suggested for the conversion of DL-hydroxyproline to glutamic and aspartic acids. D. Duncan.

BLOOM, B., KIYASU, J. Y., REINHARDT, W. O. and CHAIKOFF, I. L. **Absorption of phospholipides. Manner of transport from intestinal lumen to lacteals.** *Amer. J. Physiol.*, 1954, **177**, 84-86. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Phospholipins containing ^{14}C -labelled fatty acids were prepared by feeding rats on radio-active palmitic acid dissolved in maize oil; 9 hr. later the animals were killed and the phospholipins were prepared from the homogenised liver by extraction with ethanol and ether and precipitation with acetone. Tripalmitin- ^{14}C or phospholipins dissolved in maize oil were then given by stomach tube to rats with cannulae in their intestinal lacteals. Lymph was collected for 11 to 23 hr. and the lymph lipids were analysed for total fatty acid- ^{14}C and phospholipin-fatty-acid- ^{14}C . After

lymph collection the rats were killed and their gastro-intestinal contents were added to faeces voided during the experiment, and the whole was analysed for fatty acid- ^{14}C . From the difference between the amount of ^{14}C administered and that recovered from the gut and faeces the amount of ^{14}C absorbed was calculated.

When labelled tripalmitin was administered about 3 per cent. of the lymph fatty acid- ^{14}C was present as phospholipins; the corresponding figure when ^{14}C -labelled phospholipins were given was about 20 per cent., showing that a significant amount of ingested phospholipin was absorbed before intestinal hydrolysis had taken place.

JEFFRIES, G. H. **The effect of fat absorption on the interaction of chyle and plasma in the rat.** *Quart. J. Exp. Physiol.*, 1954, **39**, 77-81. [Sir William Dunn Sch. Pathol., Oxford.]

Blood plasma from rats on stock diet containing 2 per cent. fat occasionally clarified added milky chyle *in vitro*, as described by French *et al.* (*Quart. J. Exp. Physiol.*, 1953, **38**, 101). In rats on a fat-free diet this clearing power was absent. During absorption of olive oil, clearing activity rose to a peak at 3 and 6 hr. and had disappeared 12 hr. after the meal. Incubation of plasma for 2 hr. at 37°C . destroyed the clearing activity.—D. Duncan.

4802

BORGSTRÖM, B. **The formation of new glyceride-ester bonds during digestion of glycerides in the lumen of the small intestine of the rat.** *Arch. Biochem. Biophys.*, 1954, **49**, 268-275. [Dept. Physiol. Chem., Univ. Lund, Sweden.]

Groups of fasting rats received one of the following fat preparations, 1 ml. per rat, by

stomach tube: olive oil containing 0.17 per cent. free ^{14}C -labelled palmitic acid; a mixture containing 1-mono-olein 54.6, oleic acid 45.2 and labelled palmitic acid 0.2 per cent.; olive oil containing 9.2 per cent. free ^{14}C -labelled decanoic acid; maize oil containing 5.0 per cent. ^{14}C -labelled butyric acid; 1-mono-olein. Between 1 and 3 hr. later the animals were killed and the lipids in the lumen of the small intestine were extracted and analysed for free fatty acids, mono-, di- and triglycerides; the radio-activity of each fraction was measured.

Radio-active mono-, di- and triglycerides were isolated from the intestines of the animals given olive oil plus palmitic acid and of those given monoglyceride plus palmitic acid, showing that the incorporation of free fatty acid into intestinal glyceride combination is due, at least partly, to new ester-bond formation and is not entirely due to inter-esterification. Decanoic acid was absorbed from the intestine more rapidly than palmitic acid. Butyric acid was absorbed even more rapidly than decanoic acid and none was detected in glyceride combination in the intestinal lumen. A significant fraction of mono-olein underwent intestinal hydrolysis. Fatty acids produced by hydrolysis of glycerides were absorbed more rapidly than intact glycerides.—G. A. Garton.

4803

MATTSON, F. H., BENEDICT, J. H. and BECK, L. W.
Composition of intestinal lumen lipides following the feeding of triglycerides, partial glycerides or free fatty acids. *J. Nutrition*, 1954, **52**, 575-580. [Chem. Div., The Procter and Gamble Co., Cincinnati, Ohio.]

Groups of 3 rats were fasted for 48 hr. and then given, by stomach tube, tricaprln or cottonseed oil alone or with different amounts of 2-monoglyceride, 1-monoglyceride or cottonseed oil fatty acids. After 3 hr. the rats were killed and their intestinal contents were analysed for 1-monoglycerides, 2-monoglycerides and free fatty acids.

No matter whether cottonseed oil (containing mainly C_{18} acids) or tricaprln (C_{10} acid) was given, the quantity and isomeric forms of monoglycerides formed were similar. When as much as 21 per cent. of the ingested fat consisted of 1-monoglyceride or 30 per cent. of diglyceride the composition of the intestinal lipids was little affected. When free fatty acids were given with cottonseed oil no 2-monoglycerides were found in the intestinal digestion mixture. When the acids formed 5 or 15 per cent. of the ingested mixture no increase in free acid was noted, but when the acids formed 27 and 50 per cent. of the mixture larger amounts of free acids were found in the intestinal lumen.

G. A. Garton.

HARRIS, R. S. and SHERMAN, H. **Comparison of the nutritive values of mono-, di-, and triglycerides by a modified pair-feeding technique.** *Food Res.*, 1954, **19**, 257-262. [Dept. Food Technol., Massachusetts Inst. Technol., Cambridge, Mass.]

Groups of weanling rats were given mono-, di- and triglycerides and a mixture of the 3 fats as 15 and 25 per cent. of a synthetic diet or as 15 per cent. of a diet of natural foodstuffs. The animals were pair-fed for 70 days; the food intake of the test groups was slightly restricted and the control groups were fed on the same level. The triglycerides consisted of a mixture of partly hydrogenated soya bean and cottonseed oils; the mono- and diglycerides were prepared from the mixture.

No significant difference was observed in body-weight gain or in gain per Cal. consumed between any of the groups, and the fats appeared to be nutritionally equivalent.—G. A. Garton.

NARAYANA RAO, M. **Nutritive value of buffalo-butter fat.** *Indian J. Med. Res.*, 1954, **42**, 29-36. [Lab. Food Technol., Indian Inst. Sci., Bangalore 3.]

Buffalo butterfat was fractionated from acetone at 28° C. (fraction 1), at 0° C. (fraction 2) and by recovery of the residue after these separations (fraction 3). Five groups each of 6 rats one month old were given diets the basis of which was a mixture of maize starch 60, casein 12, sucrose 10, salt mixture 4 and vitaminised starch 4 per cent.; the remaining 10 per cent. was supplied by the whole butterfat, by one of the 3 fractions or, in a no-fat group, by extra starch. Feeding to appetite continued for 6 weeks with records of food consumed; at the end of that time the rats were killed and livers were analysed for vitamin A and lipids.

Growth was best with fraction 3 as source of glyceride, was less but similar with fraction 2 or the whole fat, and least with fraction 1 or with no added fat. Fraction 3 favoured storage of vitamin A in the liver to a degree almost equal to that of the

N.A. and R., October, 1954

whole fat; fractions 2 and 1 were less favourable in that order. Lipids in the liver did not differ significantly in amount.

From estimation of the iodine values of the fractions their nutritive values were found to increase in parallel with their degree of unsaturation.—D. Harvey.

4808

CUNNINGHAM, H. M. and LOOSLI, J. K. **The effect of fat-free diets on young dairy calves with observations on metabolic fecal fat and digestion coefficients for lard and hydrogenated coconut oil.** *J. Dairy Sci.*, 1954, **37**, 453-461. [Lab. Animal Nutrit., Cornell Univ., Ithaca, N.Y.]

Dairy calves fed on a fat-free synthetic milk from 1 or 2 days of age developed leg weakness and muscular twitches within 1 to 5 weeks, and died unless fat was supplied. The condition was cured by 4 per cent. and prevented by 2 per cent. lard added to the milk. Two per cent. hydrogenated coconut oil also prevented the condition, and it was concluded that the early deaths were not due to deficiency of essential fatty acids. The study suggested that the calf's body stores of essential fatty acids at birth are sufficient for several months, but diet fat is necessary for the first few days of life.

Total plasma lipid values varied directly with the amount of fat in the diet, but linoleic and arachidonic acids were lower in calves getting hydrogenated coconut oil or fat-free diets than in those getting lard. The diet had no effect on plasma linolenic acid values.

The percentage digestibility of lard at 2, 4, 6 and 11 weeks was 72.6, 77.0, 92.5 and 93.7, and of coconut oil 86.4, 84.7, 85.5 and 71.9, respectively. The excretion of metabolic faecal fat during the seventh and eighth weeks on a fat-free diet was from 19 to 29 mg. daily per kg. bodyweight.

4809

LAMBERT, M. R., JACOBSON, N. L., ALLEN, R. S. and ZALETEL, J. H. **Lipid deficiency in the calf.** *J. Nutrition*, 1954, **52**, 259-272. [Iowa Agric. Exp. Stat., Ames.]

Twenty dairy calves were removed from their dams at birth or after a short suckling period and were then fed on a semi-synthetic milk containing lactose 5.0, casein 3.5, fat 0 to 3.0 and salts 0.2 per cent., with vitamins and, in some of the fat-containing preparations, lecithin. In one group 5 calves received the fat-free semi-synthetic milk for 8 weeks and 3 for 12 weeks. Other groups of calves received the same synthetic milk into which had been incorporated hydrogenated soya bean oil, butter fat or free fatty acids (Emersol 9305).

Vol. 24, No. 4

The calves were weighed weekly and blood samples were taken for estimation of total fatty acids, "Allen fat", phospholipins and linoleic, linolenic and arachidonic acids.

After 3 weeks on the lipid-free diet a marked retardation of growth was noted; after 8 weeks about half the calves showed signs of lipid deficiency, including diarrhoea, scaly dandruff, long, dry hair and loss of hair on the back, shoulders and tail. Recovery was readily promoted by adding butterfat or hydrogenated soya bean oil and lecithin to the synthetic milk; response was less when hydrogenated soya bean oil was given without lecithin.

Plasma fat, total fatty acids, phospholipins and linoleic acid were significantly lower in calves fed on the lipid-free milk than in calves given fat. There was little difference in the plasma content of linolenic and arachidonic acids.—G. A. Garton.

4810

HANSEN, A. E., SINCLAIR, J. G. and WIESE, H. F. **Sequence of histologic changes in skin of dogs in relation to dietary fat.** *J. Nutrition*, 1954, **52**, 541-554. [Dept. Paediat., Univ. Texas Med. Branch, Galveston.]

Eight littermate puppies and 4 littermate dogs aged 10 months were maintained as before (Hansen and Wiese, *Texas Rep. Biol. Med.*, 1951, **9**, 491). At 6 weeks of age 4 of the 8 puppies were given the control diet containing 29 per cent. of the energy as fresh lard and 4 the low-fat diet in which fat provided 1 per cent. of the energy. The 4 dogs had previously been maintained on the low-fat diet for 9 months and showed typical signs of fat deficiency; 3 were given diets in which 29 per cent. of the energy, previously provided by sucrose, was replaced by energy from fat in the form of fresh lard, cocoa butter and an oil emulsion; the fourth remained on the low-fat diet. At intervals of 4 weeks skin samples were taken from the thigh and chest of each animal for microscopic examination.

Details are given of the histological structure of the skin of the control and fat-deficient puppies and of that of the dogs recovering from fat deficiency. The maximum changes which occurred during deficiency were visible within 6 months; there was remarkable uniformity in the changing microscopic appearance of the skin during increasing deficiency states and recovery therefrom. Alterations in stratum corneum, collagen structure, cellular infiltrate of the dermis, hair follicles, sebaceous glands and sudoriparous glands were all related to changes in epidermis and particularly to the number of cell layers. Restoration to normal was most rapid when the fat in the diet was high in unsaturated fatty acids.—G. F. Garton.

- PIERCE, F. T. (Jr.) **The interconversion of serum lipoproteins in vivo.** *Metabolism*, 1954, **3**, 142-153. [Div. Med. Phys., Univ. California, Berkeley 4.]

Lipoproteins of classes S_f 5 to 15, 15 to 20 and 20 to 100 were isolated from the blood of normal rabbits fed on stock pellets supplemented with cholesterol, and of classes S_f 100 to 400 and 400+ from alloxan-diabetic rabbits fed on the same diet. The lipoprotein fractions were injected into normal rabbits, from which blood samples were taken at intervals from 5 min. to 14 days afterwards.

Lipoproteins of all the other classes were gradually converted into S_f 5 to 15, with a peak of conversion 18 to 24 hr. after injection. There was never conversion from a lower to a higher class. With each step in conversion from a high to a lower class part of the lipoprotein disappeared; i.e., an injection of S_f 100 to 400 lipoprotein was followed by a smaller increase in 20 to 100 and a still smaller increase in 15 to 20. The disappearance of injected S_f 5 to 15 lipoproteins was slower than conversion of higher to lower classes.—D. Duncan.

- CONIGLIO, J. G., ANDERSON, C. E. and ROBINSON, C. S. **Disposition of biosynthesized fatty acids in normal and fasted rats.** *Amer. J. Physiol.*, 1954, **177**, 69-72. [Dept. Biochem., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

Radio-active acetate was injected intravenously into 2 groups of rats which had been fed on dog chow to appetite before the injections or fasted for 72 hr. All animals were then allowed to eat a fat-free, high-carbohydrate diet until they were killed 24 hr. later. Lipids were extracted from tissues and fractionated as previously described (Abst. 693, Vol. 21). The distribution of labelled fatty acids between neutral fat and phospholipins was noted.

No significant difference was observed between fasted and fed animals. In the liver the ratio of labelled neutral fatty acids to phospholipin fatty acids was about 1.0, though intestinal phospholipin fatty acids had a higher specific activity than the acids of the neutral fat. The ratios in intramuscular and subcutaneous fat (1 to 2 and < 1 , respectively), showed that a different type of association of lipids was found in these fat depots. The total ^{14}C excreted as faecal fatty acids was similar in starved and fed groups, but the specific activity of the fatty acids was greater in the starved rats.—G. A. Garton.

4818

- HAGEN, P. and ROBINSON, K. W. **Observation on the metabolism of short chain saturated fatty acids by guinea-pig caecal tissue.** *Austral. J. Exp. Biol. Med. Sci.*, 1954, **32**, 129-132. [Dept. Physiol., Univ. Queensland.]

Guineapig caecal tissue was incubated at 37°C. in Krebs Ringer phosphate buffer at pH 7 in the presence of the Na salts of acetic, propionic, butyric, valeric, caproic and heptonic acids. Oxygen consumption was measured and ketone body production estimated after 3 hours' incubation.

Small quantities of ketone bodies were produced in the absence of the salts of fatty acids; the formation of ketone bodies was increased in the presence of butyrate and caproate. Propionate was antiketogenic. Oxygen consumption was increased in the presence of butyrate and, to a less extent, in the presence of caproate.

- WEITZEL, G., SCHÖN, H. and KALBE, H. **Fütterungsversuche mit normalen und verzweigt-kettigen Fettsäureamiden. [Feeding experiments with amides of normal and branched-chain fatty acids.]** *Hoppe-Seyler's Ztschr.*, 1953, **295**, 173-187. [Biochem. Abt., Med. Forschungsanst., Max-Planck-Gesellsch., Göttingen.]

Dogs were fed on amides and N-methylamides of *n*-decanoic and *n*-dodecanoic acids and amides of 2-methylnonanoic, 4-methyldodecanoic, 2-methyltridecanoic and 5-methyltetradecanoic acids. Unabsorbed amides were estimated in the faeces and breakdown products were extracted from the urine with ether, esterified and separated by paper chromatography.

The N-methylamides of decanoic acid and dodecanoic acids were better absorbed than the corresponding normal amides. Methyl branched-chain amides produced a greater excretion of dicarboxylic acids in the urine than did the straight-chain amides. The succinic acid excreted in the urine after straight-chain and to a lesser extent after branched-chain acid amides exceeded the amount usually present in normal urine.—W. Godden.

HOLMAN, R. T. and GREENBERG, S. I. **Polyethenoid fatty acid metabolism. 7. Effect of oxidized linoleate preparations.** *Arch. Biochem. Biophys.*, 1954, **49**, 49–57. [Hormel Inst., Univ. Minnesota, Austin.]

Weanling male rats of the Sprague Dawley strain were fed on a fat-free diet for 2 months, by which time moderately severe signs of fatty acid deficiency were apparent. The animals, in groups of 4, were then given daily supplements for several weeks of ethyl linoleate, ethyl linoleate plus benzoyl peroxide, partly oxidised ethyl linoleate, ethyl linoleate peroxide, decomposed linoleate peroxide, reduced linoleate peroxide or conjugated ethyl linoleate. The rats were weighed periodically and water consumption was recorded; skin changes were recorded. At the conclusion of the feeding experiments the animals were killed and total carcass fatty acids were isolated; polyunsaturated fatty acids were estimated spectrophotometrically.

All the supplements which included ethyl linoleate, with or without peroxide, cured the fat deficiency signs and stimulated arachidonic acid synthesis. Animals given diets containing linoleate peroxide, reduced linoleate peroxide, decomposed linoleate peroxide and conjugated linoleate failed to synthesise arachidonic acid, their skin signs became more severe, growth was retarded and water consumption remained high. All these substances have in common conjugated double-bond systems. (For earlier papers in this series see Abst. 805, Vol. 19; 682, Vol. 20; 695, Vol. 21; 2439, Vol. 22 and 2934, Vol. 23.)

against multiple sublethal doses of X-irradiation in the rat. *J. Nutrition*, 1954, **52**, 637–643. [Dept. Biochem. Nutrit., Sch. Med., Univ. S. California, Los Angeles.]

Individually caged young male albino rats of the University of Southern California strain were fed from weaning on a fat-free diet until signs of essential fatty acid deficiency appeared. The animals were then distributed into 4 groups and kept on the same fat-free diet supplemented for 8 weeks in 3 groups with 10, 50 or 100 mg. ethyl linoleate per rat daily. Each group was then exposed to X-rays, 200 r weekly for 10 weeks; during and after exposure the supplementary feeding with linoleate was continued.

The percentage survival of rats in all groups which received linoleate was greater than in an unsupplemented control group and increased progressively with the amount of linoleate administered. It was concluded that the optimum amount required for protection against X-rays was about the same as that required to promote normal growth of young rats, *i.e.*, somewhat greater than 100 mg. ethyl linoleate per rat daily.

HUTCHENS, T. T., VAN BRUGGEN, J. T., COCKBURN, R. M. and WEST, E. S. **The effect of fasting upon tissue lipogenesis in the intact rat.** *J. Biol. Chem.*, 1954, **208**, 115–112. [Dept. Biochem., Med. Sch., Univ. Oregon, Portland.]

Groups of 3, 5, 2 and 2 adult male rats of the Sprague Dawley strain were fed as previously described (Abst. 2435, Vol. 22) and fasted for 1, 18, 96 and 240 hr., respectively. After fasting, the animals were each injected intraperitoneally with 22 μ C. acetate-1-¹⁴C; they were then confined in a narrow chamber which permitted little body movement. Four hr. later they were killed and the incorporation of labelled acetate into total fatty acid and total cholesterol fractions of the liver, gut, carcass and skin is reported.

All the tissues studied showed significant decreases in lipogenesis from acetate with extended fasting. Liver was the least active; the specific activities of both fatty acid and cholesterol fractions of gut lipids were notably high.

NIWA, M. **The effect of some substances on the starvation ketosis.** *Kitasato Arch. Exp. Med.*, 1953, **26**, 113-119. [Dept. Med. Chem., 2. Nat. Hosp., Tokyo.]

In groups of 4 female rats weighing from 120 to 180 g., ketosis was produced by fasting for 48 hr. Total ketone bodies were estimated by the method of Greenberg and Lester (Abst. 878, Vol. 14) in blood taken by cardiac puncture before and 1 and 2 hr. after injection of 0.4 ml. of a 1.5 M solution per 100 g. bodyweight of the K salts of several substances. Total fat and glycogen were estimated in the liver.

Succinate, fumarate and malate caused the total ketone bodies in the blood to decline by 30, 33 and 35 per cent., respectively. L-Aspartate, DL-aspartate and L-glutamate caused declines of 30, 16 and 36 per cent. With glucose, 0.75 M, the decrease was 35 per cent., but with 1.5 M KCl there was no effect. In individuals there was some direct correlation between the amount of fat in the liver and the amount of ketone bodies in the blood. Injection of CCl_4 decreased the total ketone bodies in the blood by 48 per cent.

McLEAN, J. R. and BEVERIDGE, J. M. R. **Hepatic necrosis induced by dietary means. 8. The effect of feeding a diet free from fat at successive intervals to groups of weanling rats.** *J. Nutrition*, 1954, **52**, 499-506. [Dept. Biochem., Queen's Univ., Kingston, Canada.]

The diet low in methionine, cystine and α -tocopherol resembled that described earlier (Abst. 749, Vol. 23), but for different groups of rats it contained no fat or 5 or 7 per cent. lard.

In the first experiment none of 5 rats on fat-free diet developed liver necrosis in 172 days; with 5 per cent. fat all 5 rats died of liver necrosis in 38 to 157 days. In later experiments of slightly shorter duration, 104 to 126 days, some rats in each group on fat-free diet developed liver necrosis, and the incidence appeared to increase; 1 of 10, 3 of 10, 8 of 9 and 4 of 10 in successive experiments. The result does not agree with that reported earlier (loc. cit.). The percentage of necrosis and the

mean time of survival were identical in rats receiving fat in all these experiments.

It is suggested that changes in the intestinal flora might affect the incidence of liver necrosis.

BERNHARD, K. and RITZEL, G. Beiträge zur Pathologie des Fettstoffwechsels. Phytol, ein neuer lipotroper Faktor der Nahrung. [Contributions to the pathology of fat metabolism. Phytol, a new dietary lipotropic substance.] *Hoppe-Seyler's Ztschr.*, 1953, **295**, 187-197. [Physiol. Chem. Inst., Univ. Basle.]

Numerous experiments on young growing rats showed that phytol is a lipotropic factor. When given in small amounts, a dose of from 50 to 80 mg., or from 0.5 to 1.0 per cent. of a choline-free, carbohydrate-rich diet, it prevented or largely reduced the occurrence of fatty liver, which normally follows the intake of such a diet. Liver cholesterol remained within normal limits, but there were highly significant differences in neutral fat content of the liver between the control animals and those receiving phytol. This effect of phytol was demonstrated in both prophylactic and curative experiments. Isophytol also was effective, but oleyl alcohol was not. The lipotropic effect of phytol was confirmed by partial liver removal; the increase of total lipids in 13 rats after operation was on the average only 38 per cent. compared with 115 per cent. in controls. In explanation it is suggested that phytol plays the part not so much of a methyl donor as of an accelerator of the oxidation of fatty acids in the liver.—M. B. Richards.

WARD, J., HASLAM, R. and SCHIFF, L. **Effect of choline deficiency and hepatic cirrhosis on absorption of fat in the rat.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 401-404. [Dept. Int. Med., Sch. Med., Univ. Cincinnati, Ohio.]

Young rats of Wistar strain were fed on the choline-deficient diet described by Hartroft *et al.* (Abst. 3240, Vol. 23); 13 rats received the diet for 72 days and 12 for 225 days. Pair-fed control animals were given the same diet with 15 mg. choline daily. After receiving the experimental diet the rats were fasted for 72 hr. and then each was given 1.3 g. cottonseed oil by stomach tube. Six hours later they were killed and the fat and free fatty acid contents of the digestive tract were

estimated. Lipids were estimated in blood taken from the heart, and the liver was examined microscopically.

Severe and prolonged choline deficiency, which manifested itself in fatty vacuolisation and cirrhosis of the liver, did not affect the rate of absorption of oil, the extent of intestinal hydrolysis or the level of serum lipids.—G. A. Garton.

PITTONI, A. and ROSSI, C. R. Sul meccanismo d'azione dei fattori lipotropi. [Mode of action of lipotropic substances.] 3. Influenza della colina sul metabolismo intermedio dei lipidi nel fegato. [3. Influence of choline on intermediate metabolism of fats in the liver.] 4. Metabolismo lipidico epatico, metionina e inositolo. [4. Fat metabolism in the liver, methionine and inositol.] *Arch. Sci. biol., Bologna*, 1954, **38**, 26–32; 47–55. [Ist. Chim. Biol., Univ. Padua.]

See Title 4762, Vol. 23, and Abst. 2094, Vol. 24.

3. In rats on high-fat diet, 10 mg. choline daily caused in the liver increased oxygen consumption, and decreased R.Q. and total ketone bodies. It is suggested that choline increases the oxidation of fatty acids to ketones in the liver, and also increases glucose formation, but lipocaic favours the synthesis of ketones to glucose without intervening in the breakdown of fatty acids.

4. Methionine and inositol given by mouth to rats on a high-fat diet were similar in their action, causing a decrease in production of acetoacetic acid and of total ketone bodies, but no variation in the intensity of respiratory exchange or R.Q. The smallest effective doses were 10 mg. methionine and 5 mg. inositol daily.

These results indicate increased transformation of ketone bodies to glucose, a process involving neither consumption of oxygen nor production of CO₂. Comparing the effects of lipocaic, choline, methionine and inositol, it is concluded that they have only one action in common, that of increasing the transformation of ketone bodies to glucose. Lipocaic inhibits also the transformation of carbohydrates to lipids, and choline increases the oxidation of fatty acids to ketone bodies.

4833

SHILS, M. E. and STEWART, W. B. Development of portal fatty liver in rats on corn diets ;

Vol. 24, No. 4

response to lipotropic agents. *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 298–303. [Sch. Pub. Health, Columbia Univ., New York.]

Rats on a diet containing 76 per cent. maize and 3 per cent. casein consistently developed fatty livers, with accumulation of lipid predominantly in the portal areas. On a diet in which casein was the only protein and choline was lacking, rats of the same strain developed fatty livers with the lipid localised in the central areas. The preponderance of portal fat seemed to be related to the presence of maize in the diet. Methionine, choline and vitamin B₁₂ supplements reduced the liver lipid, but the effectiveness of vitamin B₁₂ varied in different animals, and methionine did not completely prevent accumulation of fat.

It is hoped that the ability to produce the portal type of fatty liver in the rat may help in the study of kwashiorkor.—M. B. Richards.

ROSENMAN, R. H., FRIEDMAN, M. and BYERS, S. O. Intestinal absorption of cholesterol by the nephrotic rat. *Circulation Res.*, 1954, **2**, 256–257. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

Seven-week old male rats of the Long Evans strain were used ; 1 group was rendered nephrotic by the intravenous injection of rabbit anti-rat-kidney serum. Ten days later these animals and a control group had cannulae inserted in their thoracic ducts. Each rat then received 100 mg. cholesterol dissolved in 3 ml. olive oil and thoracic lymph was collected for 2 following 24-hr. periods. Total cholesterol was estimated in the plasma before cannulation and subsequently in the thoracic lymph.

The results showed diminished absorption of cholesterol in nephrotic rats which could not be accounted for by decreased lymph flow or by deficiency of bile or bile acids.—G. A. Garton.

ROSENMAN, R. H., BYERS, S. O. and FRIEDMAN, M. The effect of soybean sterols on the absorption of cholesterol by the rat. *Circulation Res.*, 1954, **2**, 160–163. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

Adult male rats of the Long Evans strain were used. In acute experiments 14 animals with

thoracic duct cannulae were divided into 3 groups. At post-operative intervals of 24 and 48 hr. each of the animals in the control group received 3 ml. olive oil by stomach tube and each rat in the other 2 groups received 100 mg. soya bean sterols, mainly sitosterols, dissolved in 3 ml. olive oil. The control animals, group 1, were then given 100 mg. cholesterol in 3 ml. olive oil; the rats of group 2 each received 100 mg. cholesterol plus 100 mg. soya bean sterols in 3 ml. olive oil, and the rats of group 3 were each given 100 mg. cholesterol plus 500 mg. soya bean sterols in 3.5 ml. olive oil. Thoracic lymph was collected for 2 following 24-hr. periods from groups 1 and 2 and for 24 hr. from group 3 and were analysed for total cholesterol.

The total lymph cholesterol during the first 24 hr. was much the same in the lymph collected from the animals of all 3 groups.

In further experiments chronic high blood cholesterol was induced in rats by feeding them on a diet containing 2 per cent. cholesterol and 1 per cent. cholic acid. When this diet included also either 2 or 10 per cent. of soya bean sterols no protective effect on the development and severity of the high blood cholesterol was apparent.

SCHWENK, E., TODD, D. and FISH, C. A. **Studies on the biosynthesis of cholesterol. 6. Companions of cholesterol- C^{14} in liver perfusions, including squalene- C^{14} , as possible precursors in its biosynthesis.** *Arch. Biochem. Biophys.*, 1954, **49**, 187-206. [Worcester Found. Exp. Biol., Shrewsbury, Mass.]

Pig liver, 15 kg., was perfused with a mixture of pig's blood and White solution containing 15 mC. of carboxyl-labelled Na acetate- ^{14}C . The tissue was then hydrolysed with KOH and the unsaponifiable matter was extracted. It was dissolved in pentane and chromatographed on alumina, yielding *inter alia* 4 fractions which were given to rats; 3 of the fractions were converted to cholesterol. From one of them pure radioactive squalene was isolated.

It was concluded that, besides squalene, a number of other intermediates in the biosynthesis of cholesterol from acetate are present in the unsaponifiable matter of the perfused liver and possibly also in normal liver.—G. A. Garton.

FEIGENBAUM, L., BYERS, S. O. and FRIEDMAN, M. **Role of reticulo-endothelial system and disposition of dietary cholesterol in various mammalian species.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 530-533. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

Twenty-eight male rats of the Long Evans strain were each given 100 mg. cholesterol in 3 ml. olive oil by stomach tube on 2 successive days; of these 28, 13 received also 0.5 ml. of 20 per cent. Indian ink intravenously twice daily for 2 days. Similarly, of 18 male rabbits which were each given in the same form 400 mg. cholesterol per kg. bodyweight by stomach tube daily for 2 days, 10 received also 5 ml. of 20 per cent. Indian ink suspension intravenously daily for 2 days, and of 15 mature dogs, each of which was given 0.6 g. cholesterol in 10 ml. olive oil per kg. bodyweight by stomach tube daily for 2 days, 8 received also an intravenous injection of 1 ml. of 20 per cent. Indian ink solution per kg. bodyweight daily for 2 days. Blood samples were taken before and 48 hr. after the beginning of experiment and were analysed for total cholesterol and total lipids; chylomicron counts were also made.

The plasma lipid of all 3 species was similarly affected by the combination of ink injection and cholesterol administration; there was a marked increase in plasma cholesterol and total lipid content. In the rats and dogs given cholesterol alone, chylomicrons were absent from the plasma, but in the rabbits many were present; in all species large numbers of chylomicrons were observed in the plasma after cholesterol administration

N.A. and R., October 1954

combined with Indian ink injections. It is suggested, therefore, that the reticulo-endothelial system plays an essential part in the transport of exogenously derived cholesterol.—G. F. Garton.

4843

FRIEDMAN, M., BYERS, S. O. and ROSENMAN, R. H. (with GUNNING, B.) **Observations concerning the production and excretion of cholesterol in mammals. 12. Demonstration of the essential role of the hepatic reticulo-endothelial cell (Kupffer cell) in the normal disposition of exogenously derived cholesterol.** *Amer. J. Physiol.*, 1954, **177**, 77–83. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

For earlier papers of the series see Absts. 4675, Vol. 23; 2085 and 3179, Vol. 24.

Groups of rats were fed on basal diets supplemented with cholesterol given by stomach tube; other groups of rats were similarly treated but were given, in addition, peripheral or portal intra-venous injections of colloidal suspensions (e.g. Indian ink, chromium phosphate, iron oxide) to interfere with the functioning of the Kupffer cells of the liver. The animals were killed at intervals after treatment and the Kupffer cells were examined histologically for the presence of cholesterol; the blood was examined for the presence of chylomicrons and plasma cholesterol was estimated.

Cholesterol was detected in the Kupffer cells within 6 hr. after administration; more was found in these cells after 24 hr. and it was also present in hepatic cells. Injection of the colloidal suspensions led to reduction of deposition of cholesterol in the liver, to persistence of peripheral chylomicrons and to high values for plasma cholesterol.

It is concluded that the Kupffer cells play an important part in the normal disposition of dietary cholesterol.—G. A. Garton.

4844

SHULL, K. H., MANN, G. V., ANDRUS, S. B. and STARE, F. J. **Response of dogs to cholesterol feeding.** *Amer. J. Physiol.*, 1954, **176**, 475–482. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Ten dogs were fed for several months on fixed daily amounts of synthetic diets containing 20 per cent. casein or α -protein and from 1 to 30 per cent. cholesterol. Total serum cholesterol and lipoproteins were estimated periodically in blood taken from animals in the post-absorptive state. Four of the dogs were examined *post mortem*.

In spite of the fixed daily cholesterol intakes, serum cholesterol levels in all the animals varied widely from week to week. There was great individual variation in the relation between the amount of cholesterol ingested and the serum cholesterol. No arteriosclerosis was found in the

4 animals examined after 11 to 22 weeks with grossly elevated blood cholesterol and lipoproteins. G. A. Garton.

4845

BOULANGER, P., PLUMMER, P. J. G., ANNAU, E. and RICE, C. E. **Parallel studies of complement and blood coagulation. 10. The effect of a high cholesterol diet.** *Canad. J. Comp. Med.*, 1953, **17**, 403–405. [Div. Animal Pathol., Canada Dept. Agric., Animal Dis. Res. Inst., Hull, Que.]

Guineapigs received for several months a pellet diet with added cholesterol in cottonseed oil. When they died or were killed all had moderate to severe fatty infiltration of the liver. Total and free cholesterol in the blood were above normal, but complement titres were not below those of controls; titres of the whole colony were low. Clotting times were prolonged in all animals, and just significantly longer in those receiving cholesterol.

It is concluded that the control of complement titre and blood coagulability by the liver were not affected by fatty infiltration.—D. Duncan.

4846

LIJO PAVIA, J. **Fondo de ojo en la hipercolesterolemia experimental. [Fundus of the eye in experimental hypercholesterolaemia.]** *Rev. Asoc. méd. argent.*, 1954, **68**, 9–13.

Four dogs were given a milk diet with additions of from 1 to 6 g. cholesterol daily. There were two constant manifestations in the fundus of the eye: arterial constriction, which was slowly reversible, and precipitation of crystals of cholesterol in the retina, which was rapidly reversible. Arterial constriction was the first sign to appear. If preventive measures were not taken it gradually intensified and persisted to the end of the experiment, which lasted 16 weeks. Crystals of cholesterol appeared in the retina between the third and fourth week, disappeared in 3 to 5 weeks when cholesterol ingestion was stopped, and reappeared 3 weeks later if it was resumed. In one dog given injections of a lipotropic substance there was no reappearance of the crystals.—M. B. Richards.

STRISOWER, B., GOFMAN, J. W., GALIONI, E. F., ALMADA, A. A. and SIMON, A. **Effect of thyroid extract on serum lipoproteins and serum cholesterol.** *Metabolism*, 1954, **3**, 218-227.

Thyroid extract was given to 19 schizophrenic patients aged from 19 to 49 years and 4 young normal subjects. Of the 19 patients, 11 completed the course of treatment, which consisted of one week on a dose of $3\frac{1}{2}$ grains desiccated thyroid daily, one week on 7 grains daily and 9 weeks on 10 grains daily. The other 8 patients had smaller amounts and the 4 normal subjects were given 3 grains daily for 2 to 3 weeks. Serum cholesterol was estimated by the method of Colman (to be published) and lipoproteins by an ultracentrifuge method.

During thyroid administration in all subjects serum cholesterol fell significantly; if returned to pre-treatment level when exogenous thyroid was withdrawn. In the 19 schizophrenics lipoproteins S_1 0 to 12 and 12 to 20 also fell. In the normal subjects S_1 0 to 12 lipoproteins fell but the effect on S_1 20 to 400 was not so significant.

In the 11 patients who took the full course of thyroid bodyweights fell by about 1 lb. per week during the 11 weeks, and the drop in lipotropic values may have been related to this. Protein-bound I was on the average 4 μ g. per 100 ml., showing that in that respect there was no hypofunction of the thyroid.

The suggestion is made that thyroid function may be inadequate with respect to lipid metabolism where cholesterol and lipoprotein values are high, but adequate in other respects. Alternatively, the thyroid effect on cholesterol may be pharmacological and unrelated to thyroid function. B. W. Simpson.

RAULIN, J. (with MACAIRE, I. and DE SAINTAURIN, M. A.) **Rôle de la nature des lipides alimentaires dans l'action des surcharges de cholestérol sur la croissance du rat blanc.** [Role of the nature of the dietary lipids in the action of excess cholesterol on growth of the white rat.] *Arch. Sci. physiol.*, 1954, **8**, 107-151. [Lab. Biochim. Nutrit., C.N.R.S., Bellevue, Seine-et-Oise.]

Young albino rats were fed on fat-free diets or on diets including lard, copra-fat [? coconut oil], olive oil, sunflower seed oil, linseed oil and cod liver oil or fatty acids derived from these fats, in each case with or without the addition of amorphous cholesterol, 1 or 3 per cent. of the diet. Full details of the diets are given. The growth rate of the animals was measured by frequent weighings, extending in some cases over 150 days.

Growth was stimulated when excess cholesterol was present in the lipid-deficient diet or in the diet with lard. With any of the other fats excess cholesterol caused retardation of growth. In the presence of the corresponding fatty acids excess cholesterol produced toxic signs and many premature deaths; choline, but not inositol, prevented the toxic action of the cholesterol-fatty acid diets and re-established normal growth rate.

BEHER, W. T. and ANTHONY, W. L. **Prevention of the cholesterol type of fatty livers in mice by dietary dihydrocholesterol.** *J. Nutrition*, 1954, **52**, 519-524. [Edsel B. Ford Inst. Med. Res., Henry Ford Hosp., Detroit, Mich.]

Seven groups of male albino mice each of 7 to 9 animals of the Webster strain were used. Each group was fed for 3 weeks on a basal cholesterol-free diet supplemented as required with 1 per cent. cholesterol plus 0.25, 0.5 or 1.0 per cent. cholic acid with or without 2.5 per cent. dihydrocholesterol at each level of cholic acid. At the end of the feeding period the livers were removed and analysed for total cholesterol and total β -steroids.

With increasing amounts of dietary cholic acid significantly increased amounts of cholesterol and β -steroids were found. The addition of dihydrocholesterol to the diets containing cholic acid and cholesterol caused a decrease in the amounts of cholesterol and β -steroids. Under the conditions studied, the ratio total cholesterol : β -steroid varied little.—G. A. Garton.

WOLDOW, A., CHAPMAN, J. E. and EVANS, J. M. **Fat tolerance in subjects with atherosclerosis: heparin effects upon lipemia, lipoproteins, and gamma globulin.** *Amer. Heart J.*, 1954, **47**, 568-579. [Dept. Med., Sch. Med., George Washington Univ., Washington, D.C.]

In 21 subjects with coronary artery disease, 3 hr. after a fat meal precipitable lipoproteins and

N.A. and R., October 1954

lipids in the blood were higher than in normal subjects, and they remained high after 5 hr., when in normal subjects they were returning towards fasting values. Since intravenous injection of 25 mg. heparin accelerated the clearing of fat in normal subjects and initiated the response in subjects with coronary artery disease, it appears that heparin may be active in normal fat transport. γ -Globulin concentration was reduced by heparin both *in vivo* and *in vitro*, which suggests that a heparin-globulin reaction may occur in association with the clearing of fat. The observations show the need for further investigation of the role of plasma proteins in fat transport and atherosclerosis.—M. B. Richards.

McMILLAN, G. C., WHITESIDE, J. H. and DUFF, G. L. **The effect of undernutrition on cholesterol atherosclerosis in the rabbit.** *J. Exp. Med.*, 1954, **99**, 261-274. [Dept. Pathol., Pathol. Inst., McGill Univ., Montreal.]

Groups of albino rabbits of the New Zealand strain were fed on a diet of commercial rabbit food supplemented, as required, with 0.5, 0.75 or 1.0 g. cholesterol per animal daily for varying periods of several months. The rabbits were weighed periodically and, in some experiments, serum cholesterol and serum lipid P were estimated at intervals. At the end of the experiment the animals were killed and the aortas were removed for assessment of the severity of the atherosclerotic lesions. Different experiments tested the effect of cholesterol feeding on (1) young, growing animals fed on a restricted diet, (2) young rabbits grossly underfed both before and during cholesterol feeding, (3) fully grown, mature rabbits which lost weight owing to restriction of food, and (4) rabbits which had been fed on cholesterol before food restriction.

No difference in aortic atherosclerosis was found between any of the groups fed on adequate diets and those given a restricted energy intake when the animals in both groups were given the same amount of cholesterol. No effect of undernutrition on the regression of atherosclerotic lesions was seen, although animals on restricted diet did show high blood cholesterol values.

DUFF, G. L. and MEISSNER, G. F. **Effect of choline on the development and regression of cholesterol atherosclerosis in rabbits.** *Arch. Pathol.*, 1954, **57**, 329-332. [Dept. Pathol., Pathol. Inst., McGill Univ., Montreal.]

Groups of young adult white rabbits were fed on commercial rabbit food for from 75 to 100 days; the diet was supplemented as required with 1 g.

cholesterol per animal daily and choline, 1 or 2 g. daily, was given by mouth to some of the cholesterol-fed rabbits. Blood was taken at frequent intervals for the estimation of serum cholesterol, lipid P and total fatty acids, and the animals were weighed periodically. At the end of the experimental period the aortas were removed and the degree of atherosclerosis was estimated visually.

The moderate or large amounts of choline given to the cholesterol-fed animals did not affect the development or regression of the lesions, nor did choline feeding affect the blood lipid picture.

In further experiments, choline, 3 g. per animal, was given daily for 5 months to rabbits which had previously been rendered atherosclerotic by continuous cholesterol feeding, but again no regression of the lesions was seen.—G. A. Garton.

WISSLER, R. W., EILERT, M. L., SCHROEDER, M. A. and COHEN, L. **Production of lipomatous and atheromatous arterial lesions in the albino rat.** *Arch. Pathol.*, 1954, **57**, 333-351. [Dept. Pathol., Sch. Med., Univ. Chicago, Ill.]

Middle-aged, obese, male rats in 6 groups of 21 received diets of protein and carbohydrate composition similar to the average diet of 4 men who developed coronary thrombosis. Fat, choline and cholesterol intakes differed between groups, and 1 group received thiouracil. Three rats from each group were killed after 14 weeks; after 20 weeks 6 from each group were treated to produce high blood pressure and the experiment continued for another 20 weeks.

The rats steadily increased in weight, except that in the first 6 weeks the thiouracil group lost weight and appetite, which they regained when the thiouracil was temporarily reduced from 25 to 6.25 mg. daily. The treatment with anti-rat-kidney serum, salt and deoxycorticosterone acetate to produce high blood pressure also caused loss of weight, but no decrease in food intake.

Blood pressure tended to rise gradually in all groups, and particularly in the group specially treated to induce this rise. In 29 of the 93 rats which survived to the end of the experiment fat was visible in the walls of the coronary arteries. The incidence was highest in the rats on the hypertensive regimen, but there was no significant correlation between high blood pressure and visible lesions. The pathology of the rats is fully described.

A high serum cholesterol:lipid P ratio was significantly correlated with the incidence of lesions.—D. Duncan.

ZILVERSMIT, D. B., SHORE, M. L. and ACKERMAN, R. F. **The origin of aortic phospholipid in rabbit atheromatosis.** *Circulation*, 1954, **9**, 581-585.

[Div. Physiol., Univ. Tennessee Sch. Med., Memphis.] Spanish summary.

Two groups of white New Zealand rabbits were fed for 5 months on a diet of 100 g. Purina rabbit chow per animal daily, supplemented with 1 g. cholesterol and 2.8 g. vegetable fat in the experimental group. At the end of the feeding period, 0.5 mC. of ^{32}P -labelled phosphate was administered intravenously to animals in both groups. Blood samples were taken 2, 4 and 6 hr. after the injections. After the last blood sample had been taken the animals were killed and their livers and thoracic aortas were removed for extraction of phospholipins and for the estimation of their specific radio-activity.

Increased amounts of phospholipins were found in the plasma and the aorta of the rabbits which had received cholesterol. The aortas of the cholesterol group were atheromatous and were found to effect the synthesis of phospholipins 5 times as rapidly as normal aortas. The results are discussed in relation to the mechanism of atherogenesis.—G. A. Garton.

OPDYKE, D. F. and OTT, W. H. **Influence of source of cholesterol, grade of cottonseed oil, and breed on experimental avian atherosclerosis.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 414–415. [Merck Inst. Therap. Res., Rahway, N.J.]

On an atherogenic diet containing 2 per cent. cholesterol (Merck) and 5 per cent. refined cottonseed oil, 2 different strains of White Leghorn cockerels showed 65 and 67 per cent. incidence of aortic atherosclerosis, but the incidence in New Hampshires on the same diet was only 17 per cent. The strain of White Leghorns which gave 65 per cent. incidence under the above conditions had 79 per cent. incidence when cholesterol from a different source (Armour) was used, 81 per cent. when the original cholesterol was combined with de-stearinated cottonseed oil, and 95 per cent. when this oil was used with the Armour cholesterol. Different strains of chickens appear to differ in their susceptibility to aortic atherosclerosis on the same diet, and the atherogenic effect of a high cholesterol diet is influenced by the quality of both the cholesterol and the cottonseed oil which are used.—M. B. Richards.

For part 1, see Abst. 2098, Vol. 24.

Methods were devised to record simultaneously right intraventricular pressure, electrocardiogram, phonocardiogram and pneumogram in dairy calves during continuous intravenous injection of Ca, K, Mg and oxalate.

Ca produced initial bradycardia, but terminal tachycardia and fibrillation followed. Atrioventricular block varied in severity, with occasional extrasystoles. There was a marked rise in right

ventricular systolic pressure. K produced progressive and uniform atrioventricular block and progressive decline in cardiac automaticity. P waves disappeared. Mg caused respiratory embarrassment, with atrioventricular and intraventricular conduction progressively and uniformly depressed. Ca appeared to antagonise Mg, but reciprocal antagonism was not evident. The effects of oxalate appeared to be opposite to those of Ca.—W. A. Greig.

See Abst. 3956, Vol. 24.

Control rabbits received the stock pellets described in the earlier paper. The experimental diet contained vitamin-free casein 20 or 30, maize starch 20, cellophane spangles 15, Wesson salt mixture 4, cottonseed oil in different amounts and sucrose to 100 parts, with vitamins. The salts

supplied K 0.6, Na 0.17 and Ca 0.57 per cent. Extra minerals replaced sucrose. Groups of 4 rabbits were used and experiments lasted 4 weeks.

On 20 per cent. casein diet increasing the fat content from 1 to 12 per cent. decreased growth; with 30 per cent. casein the mortality was high at all fat levels unless extra minerals were added. At both levels of casein and with 5 per cent. or more fat addition of Na 0.4, K 0.8 or Ca 0.73 per cent. gave growth rates increasing with the fat content; this was more pronounced at the higher casein level. Na and Ca were more effective than K. With 12 per cent. fat Na alone or all 3 minerals gave growth comparable to that on the stock pellets.

No explanation is found for these results.

NARAYANA RAO, M. **The effect of steam-volatile fatty acids on calcium metabolism in normal growing rats.** *Indian J. Med. Res.*, 1954, **42**, 37-42. [Lab. Food Technol., Indian Inst. Sci., Bangalore 3.]

The author's earlier work with De (see Abst. 1987, Vol. 23) was continued and 4 groups of rats, 3 of each sex, weighing 65 to 70 g., were the subjects of balance experiments in which butyric, *n*-caproic or *n*-caprylic acid formed 10 per cent. of the diet; a fourth group of control animals received no fatty acid but extra maize starch instead. The experiment continued for 7 days, after which the rats were killed and the pH of intestinal contents was measured at 3 levels, stomach and duodenum, jejunum and ileum. The utilisation of Ca was 46.8, 41.9, 40.6 and 39.1 per cent., respectively, in the control, caproic, caprylic and butyric acid groups. The trend towards alkalinity of the contents of jejunum and ileum was greater in the groups getting the acids than in the control group.

In a similar experiment in which the calcium soaps of these acids formed 4 per cent. of the diet

utilisation of Ca was 40.3, 37.7 and 36.2 per cent. for butyrate, caprylate and caproate, respectively; it was again in conditions of greater acidity that utilisation of Ca was best.—D. Harvey.

THOMAS, R. O., LITOVITZ, T. A. and GESCHICKTER, C. F. **Alterations in dynamics of calcium metabolism by intraintestinal calcium reservoirs.** *Amer. J. Physiol.*, 1954, **176**, 381-387. [Med. Centre, Georgetown Univ., Washington, D.C.]

For previous work see Abst. 659, Vol. 23; the present experiments were designed to test the relation between the degree of activity of Ca metabolism and the rate of disappearance of Ca from the plasma.

In rabbits given a diet of spinach and water the rate of disappearance of injected ^{45}Ca from plasma was significantly increased after 18 days, and the rate of faecal excretion was increased. Uptake of ^{45}Ca by bone was lower than in rabbits on stock diet. It is concluded that the spinach diet brought about diversion of ^{45}Ca from bone to intestinal tract.

The Na salt of ethylene diamine tetra-acetic acid (versene) or excess Ca given by stomach tube also caused rapid disappearance of ^{45}Ca from the blood, but short-term experiments failed to show lower ^{45}Ca uptake by bone.

When $^{45}\text{CaCl}_2$ was injected into the duodenum radio-activity in the blood reached its peak after about 20 min. From 2 to 4 hr. afterwards ^{45}Ca in blood was about 50 per cent. higher than at the corresponding time after it was given intravenously, but the disappearance curves were parallel.

Experiments were designed to test the counter-acting effect of aureomycin on growth retardation induced in rats by a single intraperitoneal injection of ^{32}P , 2 μC . per g. Animals which received the injection without aureomycin showed generalised retardation of growth, evident from measurements of both weight and tibial length. The ratios of weight gain to increase in tibial length did not differ significantly from those of the control group, and indicated that no selective inhibition of bone growth had occurred after that dose of ^{32}P . Animals given a supplement of aureomycin-HCl, 2 mg. per g. food, after injection of ^{32}P showed complete weight recovery after 42 days. Addition of aureomycin to the basal diet stimulated growth initially, but did not significantly alter the ultimate weight of the animals. In both groups which received aureomycin the ratio of weight gain to increase of tibial length was higher than in the control group for all values of tibial length. Aureomycin therefore appears to favour formation of soft tissue rather than a uniform increase in growth.—M. B. Richards.

MATHUR, M. L. and DESAI, S. V. **Studies on calcium and phosphorus in milk and feeds of Sahiwal cows from precalving period to the end of lactation.** *Indian J. Vet. Sci.*, 1953, **23**, 221-241. [Indian Agric. Res. Inst., New Delhi.]

Observations were made on the Ca and P content of milk from 4 high-, 4 medium- and 5 low-yielding Sahiwal cows from a few days before calving until the end of lactation. The Ca and P content of milk was low during the flush period of early lactation. High- and medium-yielding cows were in negative Ca and P balance longer than low yielders. Storage of Ca and P began when milk yields fell below 15 lb. daily. Different fodders in the green state or as silage had no effect on the mineral composition of the milk.

It is concluded that cows giving 20 lb. milk daily required at least 75 g. CaO and 80 g. P_2O_5 to prevent losses of these minerals.—J. N. Aitken.

4871

MATHUR, M. L. **Assimilation of phytin phosphorus by dairy cows.** *Indian J. Vet. Sci.*, 1953, **23**, 243-248. [Indian Agric. Res. Inst., New Delhi.]

Four high-yielding Sahiwal cows were given fodder to appetite and concentrates according to yield. Phytate phosphorus was estimated in food and faeces during 4 six-day periods for each animal.

The mean daily intake of phytate P was 19.6 g., 41.9 per cent. of which was recovered in the faeces. When the Ca : P ratio of the diet was high, recovery of phytate was generally high also.

TAYLOR, T. G. and MOORE, J. H. **Skeletal depletion in hens laying on a low-calcium diet.** *Brit. J. Nutrition*, 1954, **8**, 112-124. [Dept. Agric. Chem., Univ. Reading.]

Eight pullets were fed on a stock diet; during the last 10 days before they began to lay they retained fairly large amounts of Ca and smaller amounts of P, the mean ratio of Ca : P retained being 4.25 : 1. The birds were then fed on a diet containing only 0.054 per cent. Ca and 2 were killed before they had laid, and other pairs after laying 2, 4 and 6 eggs, respectively. The Ca content of the shells produced by each bird became less with each egg laid, but no egg was described as soft-shelled. Losses of mineral matter from the skeleton during laying were large; according to analyses of the skeleton and balance data, losses of Ca from 2-, 4- and 6-egg birds were 16.3, 25.2 and 38.4 per cent., respectively, of that originally present in the skeleton.

Some bones were ashed individually or in groups, and medullary tissue was separated for analysis from cortical tissue. Loss of mineral matter was greatest from ribs, sternum, ilium, ischium and pubis, coccygeal vertebrae and fibula, all of which had lost over 50 per cent. when 6 eggs had been laid. Least mineral matter was lost from the skull, metatarsus and toes. The quantity of medullary bone ash was hardly affected, nearly all the loss being from cortical tissue ash.—R. Hill.

MAGNESIUM

4876

MENAKER, W. **Influence of protein intake on magnesium requirement during protein synthesis.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 149-151. [Dept. Pathol., Coll. Phys. Surg., Columbia Univ., New York.]

The average weight gains in 10 days of protein-depleted adult rats on diets containing 7 or 14 per cent. protein were, respectively, 14.3 and 36 g. when a complete mineral supplement was given, but only 12.3 and 5.8 g. when the supplement lacked Mg. The small amount of protein synthesis on the 14 per cent. level when Mg was deficient indicates that more Mg was required for normal protein metabolism when protein intake was increased from 7 to 14 per cent. At the lower level the rate of protein synthesis is slow, and it is inferred that sufficient Mg is mobilised from body stores to enable the animals on the Mg-deficient ration to gain almost as much as those on the complete supplement, but at the higher level, which gives a more normal rate of protein synthesis, the amount thus mobilised is insufficient and the effects of Mg-deficient rations on protein synthesis are revealed.—M. B. Richards.

BLAXTER, K. L., ROOK, J. A. F. and MACDONALD, A. M. **Experimental magnesium deficiency in calves. 1. Clinical and pathological observations.**

BLAXTER, K. L. and ROOK, J. A. F. **2. The metabolism of calcium, magnesium and nitrogen and magnesium requirements.** *J. Comp. Pathol.*, 1954, **64**, 157-175; 176-186. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

1. Seven calves were fed on whole milk for about 2 weeks, then on an artificial milk substitute which contained 0.5 mg. Mg or less per 100 ml., and to which Mg was added as required. Each calf received 12.5 or 19.0 mg. Mg per 100 ml. diet during a preliminary period, and this was followed by an experimental period when different animals received from 0.5 to 19.0 mg. Mg per 100 ml.

Three calves showed clinical signs of Mg deficiency and died in convulsions after 6 or 7 weeks on the experimental diet: 2 of these received only the basal diet and the other 1.64 mg. Mg per 100 ml. diet. The concentration of serum Mg had fallen to about 0.7 mg. per 100 ml. when tetany appeared and to 0.5 mg. at death.

Vol. 24, No. 4

One calf received 5.8 mg. Mg per 100 ml. diet for about 10 weeks and showed no clinical sign of deficiency, but the serum Mg fell steadily to 1.0 mg. per 100 ml. Calves which received 12.5 or 19.0 mg. Mg per 100 ml. diet were clinically normal and serum Mg remained between 2.0 and 2.5 mg. per 100 ml.

The chief lesion seen *post mortem* in affected animals was haemorrhage, particularly in the heart and great vessels. Ca and Mg were estimated in soft tissues and bone. No difference was found between the Mg and Ca contents of soft tissues from normal and deficient calves, but bone Mg was partly replaced by Ca in deficient animals.

2. Balance data for Mg, Ca and N on the calves described in the previous paper are presented.

During the 6 or 7 weeks on the low-Mg diet before death occurred each calf lost about 2 g. Mg; normal animals gained about 7 g. during the same time. Mg deficiency had no effect on Ca and N metabolism, and in normal animals the ratios Mg:N and Mg:Ca retained remained so constant that Mg retention could be calculated from Ca and N retentions.

It was estimated that about 35 per cent. of body Mg had been lost when death occurred. This was higher than the result obtained from analysis of soft tissues and bone.

The Mg requirement of a growing calf was estimated to be 16 to 18 mg. Mg per 100 ml. diet.

CONSTANT, M. A. and PHILLIPS, P. H. (with CRAIG, J. A.) **The occurrence of a calcinosis syndrome in cotton rats. 4. The effect of diet and the age of the animals on the development of the disease and on the urinary excretion of various metabolites.** *J. Nutrition*, 1954, **52**, 165-186. [Dept. Biochem., Univ. Wisconsin, Madison.]

Diets containing only 0.02 per cent. Mg produced the calcinosis syndrome in cotton rats more quickly and severely than diets containing 0.1 per cent. Mg. On the low-Mg diet phosphates appeared in urine at once and creatine excretion increased from about the second week. Supplementation with biotin, aureomycin, vitamin A, Ca pantothenate, vitamin E, Mn, Zn, or methionine, or omission of the vitamin D supplement, did not improve growth or reduce deposition of minerals in cardiac and abdominal muscles. Some supplements reduced loss of both phosphate and creatine, but less effectively than a supplement of Mg. Substitution of dextrin for sucrose in the basal low-Mg diet retarded the development of the disorder.

Besides similarities previously reported between the disorder in guineapigs and cotton rats, several other similarities were observed in the present

studies. Adults were less susceptible to calcinosis than animals either 3 weeks or 2 months old.

FIELD, H. (Jr.), SWELL, L., FLICK, D. F. and DAILEY, R. E. **Cation uptake by exchange resin in vitro and the colon as a sodium-conserving organ.** *Circulation*, 1954, **9**, 32-37. [Gen. Med. Serv., Veterans Admin. Centre, Martinsburg, W. Va.] Spanish summary.

When a carboxylic cation exchange resin was equilibrated *in vitro* with a solution of the approximate electrolyte composition found in the contents of the terminal ileum, it absorbed much more Na and much less K than was found, per g. resin, in the faeces of 5 patients over prolonged periods. It appears that the colon has power to absorb Na sufficient to overcome the affinity of the resin for Na, and that it has a role in the conservation of Na almost comparable in many patients to that of the kidney. The colon does not absorb K as actively as it does Na; it gives up large amounts of K to the resin. Neither colon nor kidney is an effective conserver of K.—M. B. Richards.

The effect of altering the electrolyte, carbohydrate and amino acid intake.** *Ann. Surg.*, 1953, **138**, 434-451 (with discussion 451-452). [Dept. Surg., W. Reserve Univ., Cleveland, Ohio.]

The studies were of 12 surgical patients of both sexes undergoing major abdominal operations, either electively or in emergency; in the former, metabolic studies were begun before the operation.

Four of 5 patients given no K lost more K than healthy subjects on K-deficient diet (Abst. 2003, Vol. 23). The greatest losses were in 2 patients with strangulated intestinal obstruction. In all, the serum K levels fell only gradually and slightly and when K was given after the third post-operative day marked K retention followed. When K was given soon after operation it failed to prevent some loss of body K, but after the first 3 to 5 days repletion was rapid, and usually an excess was stored. There was little relation between energy and N metabolism and K status. Pyruvate curves after glucose tolerance tests were higher than normal in several patients, and glucose tolerance was often disturbed, but these phenomena were thought to be due to "stress" rather than to mineral deficiency.

Patients with the highest energy intake lost least weight during intravenous feeding. It is recommended that in most patients unable to take food by mouth for more than a few days, invert sugar or fructose plus amino-acids, vitamins and minerals should be given parenterally. Moderate amounts of saline were well tolerated.—D. Duncan.

EVANS, B. M., JONES, N. C. H., MILNE, M. D. and STEINER, S. **Electrolyte excretion during experimental potassium depletion in man.** *Clin. Sci.*, 1954, **13**, 305-316. [Dept. Med., Postgrad. Med. Sch., London.]

For each of 2 healthy men there were three 9-day periods of K depletion produced by a K-low diet and administration of cation exchange resin. The same subjects and one other served as normal controls. In the normal subjects hyperventilation, osmotic diuresis from intravenous mannitol, and

ingestion of sodium bicarbonate, carbonic anhydrase inhibitor and potassium chloride increased output of K in urine. During K depletion output of K in response to these stimuli was much less. Diurnal variation in K excretion was less during K depletion than in normal controls; citrate excretion was not reduced.—F. C. Aitken.

4886

SCHWARTZ, W. B., LEVINE, H. D. and RELMAN, A. S. **The electrocardiogram in potassium depletion. Its relation to the total potassium deficit and the serum concentration.** *Amer. J. Med.*, 1954, **16**, 395-403. [Med. Serv., New England Centre Hosp., Boston, Mass.]

Electrolyte and N balances were studied in relation to electrocardiograms of 9 normal subjects in whom K depletion was produced by deoxycorticosterone acetate, 17-hydroxycorticosterone acetate, ammonium chloride or ammonium sulphate, and 2 patients with chronic K depletion induced by excessive use of laxatives.

No consistent correlation was found between body K stores and the electrocardiogram. The serum K concentration was a reliable guide to K depletion, the electrocardiogram was not.

BLACK, D. A. K. and MILLS, J. N. **Nocturnal electrolyte excretion after oral administration of sodium and potassium chloride and bicarbonate.** *Clin. Sci.*, 1954, **13**, 211-219. [Dept. Med., Univ. Manchester.]

Five normal men were given at bedtime 50 m. equiv. NaCl, NaHCO₃, KCl or KHCO₃ and the urinary output of electrolytes during the night was measured and compared with control output in the same subjects. H ion output, calculated as the sum of ammonium and titratable acid less bicarbonate, was depressed by both K and HCO₃ ions. Na salts did not alter other outputs consistently. K salts increased output of Na even more than output of K. KCl and KHCO₃ were equally effective. In all experiments taken together increase in output of (K + H) was positively correlated with increase in difference of (Cl—Na). Output of (K + H) when chlorides were given was higher than with bicarbonates, and with K salts (K + H) output was higher than with Na salts. There was a negative correlation between K and H outputs when a salt was given which altered the output of one of these ions.

The results are discussed.—F. C. Aitken.

LOVE, W. D., ROMNEY, R. B. and BURCH, G. E. **A comparison of the distribution of potassium**

Vol. 24, No. 4

and exchangeable rubidium in the organs of the dog, using rubidium⁸⁶. *Circulation Res.*, 1954, **2**, 112-122. [Dept. Med., Sch. Med., Tulane Univ., New Orleans, La.]

Eighteen dogs received single intravenous injections of 50 mC. ⁸⁶Rb as carbonate in 0.15 M saline and were killed 7 min. to 7 days later. Samples of body organs and fluids were taken immediately and analysed for total K by flame photometer and for ⁸⁶Rb by a Geiger Müller tube.

The rate of ⁸⁶Rb turnover varied from organ to organ, but absolute values were not considered reliable. The mean relative ⁸⁶Rb concentration (average of the ratios of organ ⁸⁶Rb : K to plasma ⁸⁶Rb : K × 100 estimated 1, 3 and 7 days after injection) varied from 102 to 191 per cent. in 28 of 30 organs, but was only 56 per cent. in femur and 55 per cent. in brain. A "lag phenomenon" resulted in higher ⁸⁶Rb specific activity in the myocardium than in plasma. It is suggested that because of the similarity of the ⁸⁶Rb and K concentrations in most organs, ⁸⁶Rb might be useful as a tracer of K in experiments requiring prolonged observation.—W. Godden.

DE LANGEN, C. D. **1. Sodium chloride and geographical pathology. 2. Sodium chloride and capillary system.** *Doc. Med. geogr. trop.*, 1953, **5**, 323-325; 325-328. [13 Maliesingel, Utrecht.]

1. The distribution is discussed of a group of diseases which are neither true deficiency diseases nor infectious or parasite infestations, but occur mostly in association with disturbances of the peripheral circulatory system. In the study of the geographical pathology of these diseases, great differences in the dietary intake of NaCl became apparent. Some peoples used no more than 4 g. daily, and others used between 10 and 20 g., which it is suggested is excessive.

2. A short general discussion of NaCl metabolism is illustrated by an experiment on a young, healthy man who was given for 14 days a daily diet of meat 1000, NaCl 15, bread 100 and cheese 30 g. and all vitamins in tablets. The capillaries, examined in the nail bed and skin of the arm and chest, became coarse and thickened. B.M.R. increased to +19 per cent., and blood pressure from 125/80 to 140/90. After a month on a diet with 2 g. NaCl daily, all the signs regressed, but they recurred to some extent when the subject took a normal diet containing 23 g. NaCl. Administration to another subject of a rice diet with a Turkish bath twice daily reduced the B.M.R. to -8 per cent., and caused dilatation of the capillaries with a sluggish flow. Addition of NaCl and suspension of the Turkish baths reversed the changes.

The author concludes that NaCl plays an important part in the physiology of the capillaries.

HELD, H. R. **Fluormedikation und Blutfluor.** [Fluorine medication and blood fluorine.] *Schweiz. med. Wochenschr.*, 1954, **84**, 251-254. [Frauenklin., Univ. Zürich.]

Fluorine was estimated in the blood of 6 subjects before and after daily treatment for from 7 to 21 days with 2.5 mg. F, followed in some by 1.5 mg. for up to 32 days. Values before treatment, in mg. F per 1000 ml., ranged from 0.185 to 0.242, and after treatment from 0.238 to 0.294. Values for persons having a diet low in F ranged from 0.172 to 0.389. The danger level is considered to lie about 0.4 mg. per 100 ml., and doses greater than 1.5 mg. daily should not be given for any length of time; 1.0 mg. daily is the dose recommended. Estimation of F in the blood of 32 mothers treated with F for from 4 to 21 days before parturition and in the blood of their newborn infants confirmed the previous finding that F passes the placenta (Abst. 920, Vol. 22). The values ranged for the mothers from 0.206 to 0.294, and for the infants from 0.199 to 0.265; in 18 the value for the infant was higher than for the mother and in 14 it was lower.—E. M. Hume.

ODELL, R. T. and KEY, J. A. **The effect of chronic fluorine intoxication upon the healing of experimental fractures in rats.** *Ann. Surg.*, 1953, **138**, 461-466 (with discussion 466). [Dept. Surg., Sch. Med., Washington Univ., St. Louis, Mo.]

Rats which were either half-grown or adult were in 2 groups; one received water to which NaF, 226 p.p.m., was added, and each animal was thought to have consumed about 4 mg. NaF daily; the other was a control group with no additional F. In all the right humerus was broken. Some of the treated animals were given F for 30 days before fracture, others were given F only from that time. Full descriptions of macroscopic, microscopic and X-ray findings at different intervals after fracture are presented. The evidence was not only of no inhibition of the rate of repair, but of some slight favourable influence on the process in the treated animals.—D. Harvey.

BIXLER, D., MUHLER, J. C. and SHAFER, W. G. **Experimental dental caries. 5. The effects of desalivation and castration on caries and fluorine storage in the rat.** *J. Nutrition*, 1954, **52**, 345-353. [Indiana Univ., Bloomington.]

Rats, male and female, aged about 26 days were grouped, 38 as controls, 32 castrated, 32 desalivated and 31 after both operations. They were given a caries-producing diet (see Abst. 5468, Vol. 20) with 0.3 p.p.m. F. After 140 days they were killed. The incidence of caries was lower by 38 per cent. in castrated rats and higher in desalivated rats by about 60 per cent. than in the control animals. In the group which had undergone both operations the number of lesions was fewer than in the desalivated group but their severity was similar. Storage of F was greatest in the control group, much lower in the castrated and desalivated groups and least after combined treatments. Desalivation by itself diminished the rate of growth in both sexes, in males more than in females.

In a second pair-feeding experiment in which 70 rats were divided into control and desalivated groups and in which the F content of the diet was 0.6 p.p.m. it was found that the difference in storage of F could be explained on the basis of total food consumption. The final weight of desalivated rats was again lower than that of controls, and further study is thought desirable.

HALLGREN, B. Haemoglobin formation and storage iron in protein deficiency. *Acta Soc. Med. upsalien.*, 1954, **59**, 79-208. [Inst. Med. Chem., Univ. Upsala.]

A new method is described for estimation of non-haemin Fe in tissues. Viviperfusion provided a method for total body Hb estimation, since only 2 or 3 per cent. of the total remained in the body of rats after successful perfusion.

A new synthetic diet poor in Fe contained, per cent., spray-dried egg white 18, sucrose 73, poppy-seed oil 5 and iron-free salt mixture 4, with vitamin supplements. Young rats grew better on this diet than on cow's milk and were highly fertile, but developed Fe-deficiency anaemia within 2 months. The Fe content was 2.5 µg. per g. diet.

Four groups of young adult rats were given this diet or the same with protein reduced to 9, 4.5 or 2.25 per cent. and replaced by sucrose, and an adequate Fe supplement. After 47 to 91 days there was a significant fall in Hb concentration in rats on the lowest protein intake. Decrease in total Hb was probably significant on 4.5 and highly significant (38.8 per cent.) on 2.25 per cent. protein diet; total Hb was more affected than Hb concentration. On 4.5 per cent. protein the rats could maintain bodyweight and N balance after adaptation. The fall in total Hb appeared simultaneously with increase in liver fat, fall in liver protein and loss of weight in kidneys and adrenals. Simultaneous deficiency of Fe in growing rats did not increase the effects of protein deficiency, but pregnancy and lactation increased its effects in adult females.

In growing rats receiving 22 per cent. protein, reduction of Fe intake to 70 µg. or less daily produced Fe-deficiency anaemia. The decreases in total Hb and in Hb concentration were about the same. Plasma Fe and storage Fe were low. Adult rats on almost Fe-free diet were able to maintain normal plasma Fe levels for some weeks because of their greater Fe stores. Disappearance of storage Fe from liver and spleen and simultaneous fall in plasma Fe indicate early nutritional Fe deficiency. The amount of storage Fe did not influence Hb formation in protein deficiency.

In protein-depleted rats cortisone or adrenocorticotrophic hormone produced a greater loss of

carcase protein, but prevented loss of total Hb and thus increased Hb concentration and plasma Fe. It is suggested that the decrease of total Hb in relation to carcase protein in protein deficiency is secondary to hormonal adaptation.

Bleeding of protein-depleted rats caused the adrenals to increase in weight.

Non-haemin Fe stores were studied in human subjects at autopsy and in bone marrow fragments obtained by sternal puncture. In 3 men who died from accidental causes the total Fe stored was estimated at about 1 g. In 5 patients with idiopathic hyperchromic anaemia there was no stored Fe.

The literature on Hb formation in protein deficiency and the etiology of idiopathic hyperchromic anaemia are reviewed.—D. Duncan.

4907

PRATT, P. T. and JOHNSON, M. E. **Marrow iron stores in anemia.** *Arch. Int. Med.*, 1954, **93**, 725-730. [Dept. Int. Med., Div. Haematol., Coll. Med., Univ. Nebraska, Omaha.]

Fe stores were estimated qualitatively by staining for haemosiderin with 20 per cent. potassium ferrieyanide and concentrated HCl. In a group of 57 marrow samples from patients with normocytic anaemia and in 11 from patients with macrocytic anaemia Fe stores tended to be high except where there was acute bleeding. In 13 samples of marrow from patients with microcytic anaemia stores were low. In 11 pregnant women they tended to decrease with Hb value. Samples of marrow from 2 patients with *polycythaemia vera* showed low stores; they became normal after treatment which restored Hb to normal. In 20 samples of marrow from patients with diseases other than anaemia, Fe stores were high in 4 and low in 3.—F. C. Aitken.

SATHE, V. and KRISHNAMURTHY, K. **The effect of organic acids on the availability of iron.** *Indian J. Med. Res.*, 1953, **41**, 447-452. [Dept. Biochem., Indian Inst. Sci., Bangalore, 3.]

Rats rendered anaemic on milk diet, with Hb levels about 6 to 7 g. per 100 ml. blood, were divided into 6 groups of 5. Autoclaved soya bean flour was given to 5 groups to provide 0.2 mg. ionisable Fe daily; a control group received ferric chloride. The rest of the diet consisted of dried whole milk supplemented with Cu and Mn, and 3 groups received 64 mg. tartaric acid, 54 mg. ascorbic acid or 60 mg. citric acid daily.

Differences in growth were not significant. All 3 organic acids improved the availability of the Fe in the soya beans, as shown by the rate of Hb regeneration.—D. Duncan.

4909

SATHE, V. and KRISHNAMURTHY, K. **Phytic acid and absorption of iron.** *Indian J. Med. Res.*, 1953, **41**, 453-457. [Dept. Biochem., Indian Inst. Sci., Bangalore 3.]

Rats rendered anaemic by a milk diet received 3 diets containing 75 per cent. rice, unpolished and 7 or 15 per cent. polished, respectively. Fe was supplied as ferric citrate.

Increase in Hb values was most rapid in the group receiving 15 per cent. polished rice and slowest with unpolished rice, and Fe storage was also least in the latter group. It is concluded that phytin P interferes with absorption of Fe.

D. Duncan.

SEEBERG, V. P., HIDALGO, J. and WILKEN, W. **Hemoglobin regeneration following oral administration of chelated iron.** *Science*, 1954, **119**, 608-609. [Res. Div., Cutter Labs., Berkeley, Calif.]

Young rats rendered anaemic by a milk diet received 0.1 mg. Fe daily, in one group as ferrous sulphate and in another as ferric sodium ethylenediamine tetra-acetate. Others received no Fe. All had Cu.

The chelated Fe was as well absorbed and utilised for Hb formation as that from ferrous sulphate. Chelated Fe given intravenously was not well utilised.—D. Duncan.

4911

CARTWRIGHT, G. E., GUBLER, C. J. and WINTROBE, M. M. **Studies on copper metabolism. 11. Copper and iron metabolism in the nephrotic syndrome.** *J. Clin. Invest.*, 1954, **33**, 685-698. [Dept. Med., Coll. Med., Univ. Utah, Salt Lake City.]

For earlier reports see Absts. 4740, 4741, Vol. 23.

In 16 patients aged from 3 to 73 years with the nephrotic syndrome, mean plasma Cu was 64 ± 20 μ g. and plasma Fe 50 ± 33 μ g. per 100 ml. compared with normal means of 116 ± 14 and 110 ± 31 , respectively. In 7 of the patients total Fe-binding capacity was 78, compared with the normal mean of 359 μ g. per 100 ml. Cu and Fe excretion in urine were above normal and were related to protein excretion, though when protein excretion was increased by intravenous injection of albumin Cu and Fe excretion increased only slightly. It is suggested that the low plasma values may be due to loss of ceruloplasmin and transferrin in the urine.—M. B. Richards.

4912

CUMINGS, J. N. **Copper storage in hepatolenticular degeneration and allied diseases.** *Proc. Roy. Soc. Med.*, 1954, **47**, 152-154. [Clin. Pathol.

N.A. and R., October 1954

Lab., Inst. Neurol., National Hosp., Queen Sq., London, W.C.1.]

Data are given for urinary excretion of Cu and amino-acids in 34 patients with different disorders. In 3 patients with hepatolenticular degeneration, with typical clinical signs and showing a Kayser Fleischer ring, the urinary excretion of Cu and of amino-acids was far in excess of normal. Examination of brain tissue from 4 patients showed that only with hepatolenticular degeneration was there any retention of Cu in the tissues. Other patients with a somewhat similar clinical picture, but without a Kayser Fleischer ring, showed no biochemical abnormality in the urine. No patient with any disease other than hepatolenticular degeneration has yet been found to have a high urinary excretion of Cu (cf. Abst. 933, Vol. 22).—M. B. Richards.

DĄBROWSKA, W., ŻEBROWSKI, L., LEZIAK, K. and BŁOŃSKA, J. Szybkość reakcji krwiotwórczej na podawanie kobaltu u kurcząt. [The effect of cobalt on the hemopoietic reactions.] *Rocz. Nauk rol.* [B], 1954, **67**, 257–268. Russian and English summaries.

Polish greenleg chickens were given, by mouth, 0.8 µg. Co per 100 g. bodyweight daily. Haemopoiesis was stimulated as early as 14 hr. after the start of treatment but in 2 weeks activity tended to return to normal. Withdrawal of the Co was followed by a fall in erythropoiesis 60 hr. later. Chickens given Co showed a growth response, but there was none if they had previously been treated with the antiseptic quinosol. It is concluded that Co has a direct effect on the erythropoietic system, but that on the microflora reduced by quinosol it had no effect beneficial to the chickens.

DZIEWIATKOWSKI, D. D. Effect of age on some aspects of sulfate metabolism in the rat. *J. Exp. Med.*, 1954, **99**, 283–298. [Hosp. Rockefeller Inst. Med. Res.]

Rats aged 10, 30 or 300 days received intraperitoneal injections of 0.3 µC. ³⁵S as Na₂SO₄ per g. bodyweight and were killed by bleeding after 12, 24, 48 or 96 hr. The concentration of ³⁵S in the pooled sera of 10-day-old rats was 3 to 5 times as high as those in the sera of 30- or 300-day rats, which were similar. A much greater proportion of the ³⁵S in the sera was dialysable in the youngest rats than in the others. A substantial proportion of the ³⁵S in the sera was bound to protein, the non-dialysable ³⁵S being associated mainly with the albumin component.

Mucopolysaccharides were isolated from the skeletons, pelts and viscera of the animals and the specific activity of the sulphate S prepared from them was measured. The highest specific activity was in mucopolysaccharides from the tissues of the youngest rats and the lowest in those from the oldest. The highest activities were obtained from rats slaughtered 12 hr. after injection and there was a slow drop in specific activity as the interval before slaughter was extended to 96 hr.

Estimation of ³⁵S in the ends and shafts of femurs and radio-autographs of the long bones support the view that the ³⁵S had been incorporated into the chondroitin sulphate of growing cartilage (Abst. 2531, Vol. 22).—W. Godden.

4919

DZIEWIATKOWSKI, D. D. Utilization of sulfate sulfur in the rat for the synthesis of cystine. *J. Biol. Chem.*, 1954, **207**, 181–186. [Hosp. Rockefeller Inst. Med. Res., New York.]

Two groups of rats were 10 days and 2 groups were 32 days old. Fourteen young and 7 older rats received a single intraperitoneal injection of carrier-free ^{35}S as sodium sulphate in water, 1 μC . per g. bodyweight. The other 2 groups received 2 such injections with an interval of 24 hr. All were killed 24 hr. after injection. The skin with hair, the internal organs, and the skeleton with musculature from the rats in each group were pooled and cystine was isolated from each sample.

^{35}S was present in all the cystine samples, and with one exception the double injection produced about twice as much isotope per mg. cystine S as did the single injection. The amount of ^{35}S in the samples was small, a millimole of the cystine sample with the highest ^{35}S content representing only about 0.02 per cent. of the ^{35}S given.

There was more ^{35}S in the skin, skeleton and muscle samples from the young than from the older rats, but the latter had more ^{35}S in the internal organs.—D. Duncan.

4920

DAVIES, D. V. and YOUNG, L. **The distribution of radio-active sulphur (^{35}S) in the fibrous tissue, cartilages and bones of the rat following its administration in the form of inorganic sulphate.** *J. Anat.*, 1954, **88**, 174–183. [St. Thomas's Hosp. Med. Sch., London.]

After intraperitoneal injection of rats with ^{35}S -labelled Na_2SO_4 there was an appreciable uptake of ^{35}S in all cartilages, but less in fibrous than in hyaline and less in white than in elastic fibro-cartilage. In epiphyseal cartilage the maximum concentration occurred in the zone of the cell columns. Both in 2-day-old and 3-week-old rats the ^{35}S was widely distributed through the tissues 4 hr. after injection, but by the tenth day it had disappeared from the fibrous tissues and from most cartilages except from the cell column zone.

In all cartilages, and more particularly in the cell column zone, much of the ^{35}S within 4 hr. was not merely held as inorganic Na_2SO_4 , but was fixed in the tissues in a form insoluble either in water or in buffer solution at pH 10. It is suggested that the inorganic sulphate had been incorporated in a component of the cartilaginous matrix.

M. B. Richards.

4921

BÉLANGER, L. F. **Autoradiographic visualization of the entry and transit of S^{35} in cartilage, bone, and dentine of young rats and the effect of hyaluronidase *in vitro*.** *Canad. J. Biochem. Physiol.*, 1954, **32**, 161–169. [Dept. Histol., Sch. Med., Univ. Ottawa, Ont.]

The distribution of ^{35}S in skeletal tissues was studied in suckling rats from 1 hr. to 6 days after a single injection of labelled sulphate.

^{35}S diffused rapidly into cartilage and was incorporated into an organic molecule, probably chondroitin sulphate, in the 48 hr. after injection. By the sixth day the ^{35}S had left the cellular elements and was in the matrix.

In bone and dentine the deposition of ^{35}S in the first few hours was apparently proportional to the degree of mineralisation, and it was removed by demineralisation. After demineralisation a thin band of radio-activity persisted along a growth line, probably again associated with chondroitin sulphate.—D. Duncan.

4922

ZIRM, K. L., KILCHES, R. and SCHREINER, H. **Über das biologische Verhalten von Metall-derivaten des Chlorophyllins. 1. Untersuchungen zur Ausscheidung von Zink-Chlorophyllin unter Anwendung von $\text{Zn } 65$. [Biological behaviour of metal derivatives of chlorophyllin. 1. Studies of the excretion of zinc chlorophyllin with ^{65}Zn .]** *Biochem. Ztschr.*, 1954, **325**, 163–169. [Lannacher Heilmittel Gesellsch., Lannach, Styria.]

When mice were injected subcutaneously with $^{65}\text{ZnCl}_2$ the Zn was very rapidly excreted, and after 60 hr. could no longer be detected in any of the organs except the intestines. After injection of ^{65}Zn -chlorophyllin-Na solution, mobilisation from the injection depot and excretion of the protein complex formed, which accumulated in the lymph nodes before transport to the blood, were very much slower. Activities were still measurable after 3000 hr. Both for ZnCl_2 and the Zn-chlorophyllin compound excretion was almost entirely through the intestines. The path of excretion of chlorophyllin derivatives is determined by the metal atom, for Co-chlorophyllin, as was previously shown (Abst. 3282, Vol. 23), is excreted almost entirely through the kidneys.—M. B. Richards.

MACHLIN, L. J., JACKSON, J. T., LANKENAU, A. H. and PEARSON, P. B. **Uptake of S^{35} in the feathers, gizzard lining, liver and muscle of young chickens after injection with radio-active methionine or sulfate.** *Poultry Sci.*, 1954, **33**, 234–238. [Bur. Animal Indust., U.S. Dept. Agric., Beltsville, Md.]

Chickens aged 3 weeks received a single intramuscular injection of 21 μC . L-methionine and were killed from 4 hr. to 36 days later. In a second experiment birds 4 weeks old received on 3 consecutive days injections of labelled methionine or sodium sulphate.

Muscle retained ^{35}S much longer than did gizzard lining or liver. Since the gizzard lining does not contain living cells, its loss of radio-activity prob-

N.A. and R., October 1954

ably represented the rate at which the tissue wears away; if so, half the lining is worn away every 5 to 10 days in young chickens. The gizzard lining had a high content of cystine and methionine.

Both methionine and sulphate provided ^{35}S for incorporation into cystine, as was shown by its recovery from feathers. Once deposited in the feathers the ^{35}S was not exchanged with body S, and ^{35}S from methionine injected into adult hens did not appear in the feathers. Growth was shown to take place only from the base of the feather.—D. Duncan.

TRIBBLE, H. M. and SCOLAR, F. I. **Zinc metabolism of young college women on self-selected diets.** *J. Nutrition*, 1954, **52**, 209–216. [Sch. Home Econ., N. Texas State Coll., Denton.]

Zinc balances were estimated in 13 subjects aged from 17 to 27 years, for 5 days on self-selected diets.

Intake varied from 9.8 to 14.4 mg. Zn daily. Mean excretion of Zn in urine and faeces was 8 and 42 per cent., respectively, of the intake. All the subjects were in positive balance and retained on the average 6.6 mg. daily.—R. Hill.

TUPPER, R., WATTS, R. W. E. and WORMALL, A. **The incorporation of ^{65}Zn into avian eggs.** *Biochem. J.*, 1954, **57**, 245–255. [Dept. Biochem., Med. Coll., St. Bartholomew's Hosp., London, E.C.1.]

Five hens were kept in battery cages and fed on stock chicken pellets, which with the grit and water provided a total Zn intake of about 5.7 mg. per bird daily. The mean total Zn content of their eggs was $310\ \mu\text{g.}$, S.E. ± 26 in the yolks with only traces in the whites and shells. The birds received intramuscular injections of a zinc-glycine complex containing ^{65}Zn ; the preparation of the complex is described.

^{65}Zn appeared in the yolks of eggs laid after the injections, but not in whites or shells. After a single injection the hens stopped laying for 3 to 7 days, except for one which laid an egg 18 hr. after injection; this egg contained no ^{65}Zn . The highest activity, representing 1.5 to 2.0 per cent. of the injected ^{65}Zn , was in eggs laid 5 to 10 days after the injection; activity then fell quite sharply until the fourteenth day, and subsequently declined slowly. The eggs of one hen were examined for 37 days after the injection, and the last one laid contained 0.5 per cent. of the injected ^{65}Zn ; the total ^{65}Zn content of the eggs in this time was 20 per cent. of that injected. All the ^{65}Zn was precipitated with the protein and especially with lipovitellin; none was bound to livetin, phosphovitin or yolk lipids. The ^{65}Zn was firmly bound to the vitellin component and could not be removed by dialysis or exchanged with that of non-radio-active zinc-glycine.—D. Duncan.

KÖHN, K. **Lymphgewebe und Milz im Tierversuch bei saurer und basischer Nahrung, bei Hunger und Hormonbehandlung.** [Lymphatic tissue and spleen in animals on acid or basic diets, starved animals and animals treated with hormones.] *Frankfurter Ztschr. Pathol.*, 1954, **65**, 5–21. [Pathol. Inst., Städt. Krankenhaus, Berlin-Spandau.]

Experiments were made on 150 guineapigs and 15 cats to test the effect of acid or basic diets, hunger, or hormone treatment on lymph tissue and spleen. The tissues were examined histologically, and observations were made of urine reaction, alkali reserve, weight of body and spleen, and circulating lymphocyte count. The experiments showed that acid or alkali diet alone caused no change in the alkali reserve or in the blood picture. By giving NH_4Cl or NaHCO_3 by mouth, or intracardially, acidosis or alkalosis was produced, with

leucocytosis or leucopenia. Histologically no influence of acid or basic diet was found on spleen or lymph tissue. Guineapigs on acid and cats on basic diets, in which appetite was poor, showed loss of weight in spleen and lymph tissue similar to the atrophy of these tissues from starved animals. In animals treated with cortisone or ACTH there was pronounced lymphopenia, with hyperplasia of reticuloendothelial tissue, but no definite centre of proliferation was found in the lymph follicle as described by Hoepke, whose work is critically reviewed in the introduction of the paper. An extensive bibliography is included.

DALE, H. E., GOBERDHAN, C. K. and BRODY, S. **A comparison of the effects of starvation and thermal stress on the acid-base balance of dairy cattle.** *Amer. J. Vet. Res.*, 1954, **15**,

197-201. [Dept. Vet. Physiol., Grad. Sch., Univ. Missouri, Columbia.]

Four cows, 2 in milk, were kept at a temperature of 60° to 70° F. and relative humidity 60 to 80 per cent. and were fed on a standard dairy ration for 6 days before being allowed only salt and water for 5 days.

Plasma concentrations of cations fell slightly during starvation, from a mean total of 177.8 to 168.2 m. equiv. per litre, but urinary output of cations fell from 4635.0 m. equiv. daily to 805.9,

showing the homeostatic power of the kidney. Total anions in plasma fell from 47.1 to 43.2 m. equiv. per litre and excretion from 5513.2 to 1691.0 m. equiv. daily. Carbonate excretion fell from 4500 to 540 m. equiv., and phosphate excretion rose from 4.2 to 824.0 m. equiv. daily. Blood *pH* and bicarbonate content remained constant. Ketone bodies in blood and urine rose sharply, in dry as in lactating cows, and excretion of organic acids declined.—D. Duncan.

MCCANCE, R. A., NAYLOR, N. J. B. and WIDDOWSON, E. M. **The response of infants to a large dose of water.** *Arch. Dis. Childhood*, 1954, **29**, 104-109. [Dept. Exp. Med., Med. Res. Council, Univ. Cambridge.]

Ten normal babies, aged from 6 to 18 days, and 7 adults were given a test dose of water equal to 5 per cent. of bodyweight or 6 per cent. of body water. The test dose led to a great and rapid increase in urine flow. The flow subsided more quickly in infants than in adults, but on the basis of body water the minute volumes attained were the same. At the height of diuresis the concentrations of Na, Cl and K in the infants' urines were the same as in the adults' urines.—F. C. Aitken.

KENNEY, R. A. **The effect of the drinking pattern on water economy in hot, humid environments.**

Brit. J. Indust. Med., 1954, **11**, 38-39. [Lab. Hot Climate Physiol. Res., Oshodi, Lagos, Nigeria.]

Six members of the Lagos labour force exercised in a chamber at a temperature of 100° F. dry bulb and 95° F. wet bulb by stepping on and off a stool 12 in. high 20 times per min. for 5 min. in each of 6 successive quarters of an hour. Each test of 90 min. was made once a week or less often. The air was in motion. The men were dried with a towel and weighed with the bladder empty before and after each test. The volume of urine passed after the 90 min. was measured. When no water was drunk during the test the men lost about 1 kg., so 1 litre was the amount of water selected to be drunk during the test. In different tests it was taken all at once just before the test or in equal fractions equally spaced 3, 6 or 9 times in the 90 min. The loss in the urine was less the smaller the interval, but in all the tests except the last one

in which 83 ml. were taken every 7½ min. more water was lost through the urine than when no water was taken at all. The non-urinary loss did not differ significantly in any of the tests. The most economical way to use a limited supply of water is, therefore, to drink small amounts frequently.

4932

TAYLOR, W. H. **Water diuresis in idiopathic steatorrhoea.** *Clin. Sci.*, 1954, **13**, 239-245. [Dept. Biochem. (Radcliffe Infirmary), Univ. Oxford.]

The diuresis after a litre of water was estimated under strictly controlled conditions which included the taking of breakfast before the water. Trials showed that in 18 patients with active idiopathic steatorrhoea diuresis was less than in normal subjects, owing to a significant delay in the time taken to reach maximum flow and to a reduction in the maximum rate of excretion. There was some overlapping of the values in the 2 series of subjects.

In 5 patients in remission diuresis was normal. In the patients with the active condition there was a significant positive correlation of the 2-hourly urine volume with the percentage fat absorption, but not with Hb level or the duration of the illness. In 18 patients with idiopathic hypochromic anaemia and in 31 patients with pernicious anaemia the results of the test were similar to those found in idiopathic steatorrhoea. The test was normal in 2 out of 4 patients with pancreatic steatorrhoea. In chronic diarrhoea of unknown origin water diuresis was found to be normal in patients without steatorrhoea but decreased in patients with steatorrhoea. These results confirm the hypothesis of Wollaeger and Scribner, which states that water is held in the intestine during prolonged digestion and absorption of food. It is suggested that this test might be useful and time-saving in assessing progress in patients with idiopathic steatorrhoea.—L. Wills.

N.A. and R., October 1954

Res., 1953, **41**, 307-309. [Clin. Res. Unit, Indian Counc. Med. Res., Sch. Trop. Med., Calcutta.]

During an outbreak in 1950 in Calcutta body fluid changes in 12 patients with epidemic dropsy were studied and compared with normal values (see Abst. 122, Vol. 23). The means, with normals in brackets, were: plasma volume 2152 (1591), blood volume 2999 (2770), red blood cell mass 857 (1179), available thiocyanate space 10,304 (7401), and interstitial fluid 7489 (5212) ml. per sq. m. body surface. Progressive changes for 3 patients are illustrated. The anaemia accompanying the disease is concluded to be the result not of blood dilution but of actual reduction in the number of circulating red cells.—D. Harvey.

METABOLISM OF OTHER SUBSTANCES

4937

CAFFARENA, G. and MERLINI, M. Rapporti tra piruvicemia materna e fetale alla nascita. [Relation between the blood pyruvic acid values of mother and child at birth.] *Lattante*, 1953, **24**, 517-520. [Ist. Clin. Pediat. G. Gaslini, Univ. Genoa.] English summary.

Pyruvic acid was estimated in the blood of 9 women as soon as possible after parturition, and in the blood of their newborn infants. The values were high; in mg. per 100 ml. they ranged for the infants from 1.15 to 1.86 and for the mothers from 1.69 to 3.43. The values for the infants were below those for the mothers and roughly followed them. The highest values obtained, 3.15 and 3.91, were for a tenth woman with severe albuminuria and her child, respectively. The other values had some direct relation to the duration of labour.

McCORMICK, M. H., HARRIS, P. N. and ANDERSON, C. A. **The role of myo-inositol in purified diets.** *J. Nutrition*, 1954, **52**, 337-344. [Lilly Res. Labs., Indianapolis, Ind.]

In a 16 weeks' growth test on young white rats of the Harlan strain addition of 10 mg. inositol to 100 g. of a diet of purified amino-acids, oil, salts, purified vitamins and sucrose had no significant effect on average weight gain or protein efficiency. There was no significant difference in average weight gain between the 2 groups of rats on the basic amino-acid diet and a group which received 19 per cent. casein instead of the amino-acids. The inositol content of the carcasses was similar in all 3 groups with little variation in the individual values; it apparently does not depend on the

intake of inositol. Gross and microscopic examination of the animals and tissues did not show any difference between the 2 groups on the basic diet.—M. B. Richards.

Transport of cations and reversion of methaemoglobin.] *Arch. exp. Pathol. Pharmacol.*, 1954, **221**, 497-505. [Inst. Pharmacol., Humboldt Univ., Berlin.]

Studies were made of the relation between the active transport of cations and the reversion of methaemoglobin in red blood cells, mainly of rabbits. It was shown that glucose supports both processes, precedence going to the reversion under normal osmotic conditions. If the red cells lose the power to reduce methaemoglobin, the maintenance of the osmotic condition of the cells is no longer assured. Lactate supports only the reversion process. Simultaneous addition of glucose and lactate supports both methaemoglobin reduction and cation transport. In hypertonic disease methaemoglobin reversion is distinctly retarded, through causes not yet explained. Differences in the osmotic behaviour of normal red cells and those containing methaemoglobin may indicate that methaemoglobin reduction is connected with a reduction of osmotic resistance.—M. B. Richards.

KERLY, M. and OTTAWAY, J. H. The effect of diet on glycogen formation in rat liver. *J. Physiol.*,

1954, **123**, 516-533. [Dept. Biochem., University Coll., London.]

Rats were fed from weaning on diets rich in carbohydrate, fat or protein and some were fasted for 24 or 48 hr. before they were killed. The glycogen content of the liver was affected by the sex of the rat and by the composition of the diet, in both fed and fasted animals. The proportion of the total glycogen extractable by 10 per cent. trichloroacetic acid was highest on the high-fat and lowest on the high-protein diet. Changes in the glycogen content of liver slices during incubation depended on the initial glycogen content. Diet affected the amount of glycogen synthesised during incubation in a glucose-containing medium, but not when glucose-1-phosphate or pyruvate was the substrate.—M. B. Richards.

4950

KERLY, M. and OTTAWAY, J. H. The effect of diet on the metabolism of glucose and of acetate by rat diaphragm muscle. *J. Physiol.*, 1954, **123**, 534-552. [Dept. Biochem., University Coll., London.]

Diaphragm muscle was taken from rats reared since weaning on diets high in carbohydrate, fat or protein and measurements were made of glycogen content, rates of uptake of glucose and acetate, oxygen consumption and lactate production during its incubation in media containing glucose or acetate, with or without added insulin.

Diet affected particularly the metabolism of recently fed rats, and fasting affected the rates of all the metabolic changes studied. Insulin significantly increased glucose uptake, glycogen formation from glucose, and oxygen consumption in presence of glucose. Muscle from female rats stored more glucose as glycogen, oxidised less glucose, and utilised more acetate, and the oxygen consumption with glucose as substrate was significantly less than in male muscle. Since there was no formation of glycogen from acetate, it was deduced that acetate could not completely replace endogenous fat as a substrate for oxidation.

BING, R. J., SIEGEL, A., UNGAR, I. and GILBERT, M. **Metabolism of the human heart. 2. Studies on fat, ketone and amino acid metabolism.** *Amer. J. Med.*, 1954, **16**, 504-515. [Dept. Med., Med. Coll. Alabama, Birmingham.]

For part 1 see Abst. 2166, Vol. 24.

Uptake by the heart of fatty acids, ketone bodies and amino-acids was studied, by the method previously described, in 33 patients, none of whom was in cardiac failure.

At blood fatty acid levels of 0.605 to 1.76 m. equiv. per cent., mean 1.105, S.D. 0.286, extraction of fatty acids ranged from 0 to 0.043 m. equiv. per cent., mean 0.016 ± 0.013 . In 8 patients studied 3 to 4 hr. after a meal of fat the heart took up 0.013 to 0.07, mean 0.028 ± 0.02 m. equiv. per cent. of fatty acids, which suggests storage of fat.

There was a negative correlation between utilisation of carbohydrate and ketone bodies.

Extraction of amino-acids from coronary blood ranged from 0 to 0.45, mean 0.132 ± 0.167 mg. per cent. of N, and the oxygen extraction ratios suggested that a considerable fraction of the oxygen consumption of the heart could be ascribed to amino-acid breakdown. When amino-acids were infused intravenously in 6 patients the 245 per cent. increase in myocardial amino-acid extraction was out of proportion to the 20 per cent. rise in blood amino-acid level. There was also a significant rise in glucose extraction.

Reasons are discussed for the large scatter shown in statistical analysis of the results. It is concluded that the heart is "geared" to the general metabolic state of the body.—D. Duncan.

KLEIN, P. D. and JOHNSON, R. M. **A study of the onset of unsaturated fatty acid deficiency in subcellular particles of rat livers.** *Arch. Biochem. Biophys.*, 1954, **48**, 380-385. [Detroit Inst. Cancer Res.]

Male rats weaned at 18 days of age were given a diet containing glucose 77, casein 18, salts 4 and vitamin mixture 1 per cent. Control animals received the same diet except that 5 per cent. maize oil was incorporated at the expense of glucose. At fortnightly intervals pairs of rats were killed and their liver tissue was fractionated into large granules, microsomes and a poorly sedimentable fraction. Lipids were extracted from each fraction and analysed for di-, tri-, tetra- and pentaenoic fatty acids.

On the fat-free diet, the di-, tetra- and pentaenoic acid content of liver cytoplasmic particles declined rapidly. The rate of decline became slow after about 6 weeks. The greatest losses were from the microsomes and the least from the mitochondria. Trienoic acid accumulated in all 3 fractions to reach 4 to 6 times the amount found in liver particles from rats on the control diet.

It is suggested that the primary changes in essential fatty acid deficiency in the rat may take place about 6 weeks before overt clinical signs appear.—G. A. Garton.

MILLER, O. J. and GARDNER, W. U. The role of thyroid function and food intake in experimental ovarian tumorigenesis in mice. *Cancer Res.*, 1954, **14**, 220-226. [Dept. Anat., Sch. Med., Yale Univ., New Haven, Conn.]

Ovarian transplants were grafted into the spleens of 109 castrated F_1 hybrid mice at 37 to 71 days of age. Of these mice, 24 controls were fed on fox chow with meat meal (Purina), 24 were rendered hyperthyroid by addition of 0.2 per cent. dried thyroid to this diet and 24 were rendered hypothyroid by addition of 0.2 per cent. thiouracil.

Inanition was induced in 37 mice by restricting the food to two-thirds of the control intake; 16 of these were fed to appetite after $4\frac{1}{2}$ to $7\frac{1}{2}$ months of restriction. The mice were killed 11 to 29 months after the experiment was begun, for histological examination of the graft, metastases, liver, adrenals, kidneys, thyroids and genital organs.

Ovarian tumours were found in 16 of 21 mice on the control diet, 3 of 20 given dried thyroid, 10 of 21 given thiouracil, 5 of 12 underfed and 12 of 14 re-fed mice. In 8 mice there was no sign of the ovarian graft. One tumour of a type previously undescribed and one tubular adenoma occurred in hyperthyroid females, but the total incidence of ovarian tumours in the thyroid-fed mice was significantly less than in any other group. Adrenal cortical hyperplasia was most extensive in the control and re-fed groups. Oestrogenic hormone and progesterone were produced in quantities sufficient to cause changes in the uterus of the tumour-bearing mice in all except the underfed group. Hepatomas occurred in 6 hypothyroid mice, 5 of which failed to develop ovarian tumours, and in none of these was oestrogenic hormone produced. Scrotal hernias occurred in 4 castrated males with tumours, one control and 3 in the re-fed group.—B. W. Simpson.

CAWLEY, R. H., MCKEOWN, T. and RECORD, R. G. Influence of the pre-natal environment on post-natal growth. *Brit. J. Prev. Social Med.*, 1954, **8**, 66-69. [Dept. Social Med., Univ. Birmingham.]

The weight and length of 334 boys and 307 girls were recorded at birth and at 3, 6, 9, 12 and 24 months of age.

Positive correlations were found at birth between weight and length on the one hand and duration of gestation and birth rank on the other. These had disappeared by 2 years of age. There was little correlation between weight and length on the one hand and maternal age on the other until 2 years of age, when a positive correlation was obtained.—F. C. Aitken.

DEL MUNDO, F. and CRUZ-ADIAO, A. **Measurements of 10,839 newborn Filipino babies (a follow-up study).** *J. Philippine Med. Assoc.*, 1953, **29**, 505-508. [The Little Clinic, Q.C.]

The study previously reported (Abst. 2058, Vol. 23) was extended to over 10,000 newborn infants from government, charity and private hospitals. The infants in private hospitals were again slightly heavier than those in other hospitals. There was no significant difference in height or in head or chest circumference from those of the first study.—A. M. Copping.

4966

THOMPSON, J. **Birth weight and weight gain at six months.** *Health Bull., Dept. Health Scot.*, 1954, **12**, 25-28.

Healthy single infants, 175 male and 163 female, born in the Simpson Memorial Pavilion of Edinburgh Royal Infirmary, were re-weighed at 6 months. Mean weights in lb. for boys and girls, respectively, were 7.48 ± 0.89 and 7.26 ± 0.88 at birth and 17.23 ± 1.91 and 15.98 ± 1.76 at 6 months. Weights at 6 months were about 2 lb. above those published in 1926 for Scottish cities (Paton and Findlay, *Med. Res. Council. Rep. Spec. Rep. Ser. No. 101*). Separation into 4 birthweight categories showed that the order of weights was unchanged at 6 months. There was no relation between birthweight and weight increment in the first 6 months; this is in agreement with the findings of Parfit (Abst. 2424, Vol. 21) and underlines his suggestion that recording of weight increments should start from a common zero base line, not from birthweight.—W. M. Deans.

4967

THOMPSON, H. **Data on the growth of children during the first year after birth.** *Human Biol.*, 1951, **23**, 75-92. [Clin. Child Development, Yale Univ.]

The raw data from an extended pre-war study of height, weight and 7 other body measurements of healthy New Haven infants, 32 male and 36 female, at 4-week intervals during the first year of life (Gesell and Thompson, "The Psychology of Early Growth", MacMillan, New York, 1938; Abst. 2220, Vol. 8) are here published for the first time, with means and standard deviations of the 4-week increments from 8 weeks onward.

MEREDITH, H. V. **North American Negro infants: size at birth and growth during the first post-natal year.** *Human Biol.*, 1952, **24**, 290-308. [State Univ. Iowa, Iowa City.]

The literature comparing weights, heights and body measurements of North American negro and

white infants from birth to 1 year is analysed, the results are tabulated and the following conclusions are drawn:

The mean birthweight of viable negro infants is 3.23 kg. (3.28 kg. for infants above 2.2 kg. at birth); of white infants, 3.35 and 3.41 kg., so that the negro infant is on the average nearly 4 per cent. lighter than the white. Negro infants receiving adequate dietary and medical care from birth weigh on the average 7.44 kg. at 6 months and 9.87 kg. at 1 year, white infants 7.64 and 10.00 kg., so that by the end of the first year the difference is reduced to 2 per cent. Negro infants are about 1.0 cm., or 2 per cent., shorter at birth than white, but with adequate care there is no difference after 6 months. Head width, stem length, trunk and hip width are smaller in negro infants than in white, both at birth and during the first year.—W. M. Deans.

4969

NORVAL, M., KENNEDY, R. L. J. and BERKSON, J. **Biometric studies of the growth of children of Rochester, Minnesota. The first year of life.** *Human Biol.*, 1951, **23**, 273-301. [Dept. Paediat., Mayo Clin., Rochester, Minn.]

This is the first of a series of reports on healthy children, mainly of North European ancestry, from the rural farming community of Rochester, Minnesota, of economic status rather above average, during the period 1934 to 1945.

Length (in.) and weight (lb.) without clothing were obtained for 2079 boys and 2032 girls under 1 year, and the results for each sex at monthly intervals are shown in graphs and tables.

Boys were not only longer and heavier than girls of the same age but also heavier than girls of the same length. The mean weights were higher than most of those recorded in the literature. Boys were more variable than girls. The correlation between length and weight rose at first and then fell slowly to about +0.6 at about the sixth month and remained about the same thereafter. Monthly weight increments were at first greater in boys than in girls but tended to equality at the end of the year. Although infants of low birthweight tended to have larger weight increments, on the whole the infants in the 6 birthweight classes retained the same relative position in respect of both length and weight throughout the year.

ACHESON, R. M. and HEWITT, D. **Oxford Child Health Survey. Stature and skeletal maturation in the pre-school child.** *Brit. J. Prev. Social Med.*, 1954, **8**, 59-65. [Social Med. Unit, Univ. Oxford.]

The Oxford Child Health Survey was described in Abst. 2569, Vol. 20 and Title 812, Vol. 23.

In the 580 pre-school children studied, stages of maturation by Todd's standards were recorded and heights of children late in reaching these were compared with those of children who reached them early. Although X-ray photographs showed a range of maturity within each stage group there was evidence that slow maturers were taller and rapid maturers shorter than the mean.

The question whether those whose maturation is held back by an unfavourable environment follow the same pattern by tending to become rather tall was also considered. Data from subgroups of children whose parents belonged to social classes I or II and IV or V of the Registrar-General's classification were examined. [The numbers in these groups are not given but if the proportions were similar to those of the total of 3682 shown in Table 1, from which presumably the 580 children were selected, the number in classes I and II and IV and V together would be of the order of 14 per cent. of the whole sample for boys and 16 per cent. for girls.] For boys both maturation and growth were slower in the poorer than in the better classes but for girls only growth was retarded.—D. Harvey.

4971

DREIZEN, S., SNODGRASSE, R. M., PARKER, G. S., CURRIE, C. and SPIES, T. D. **Maturation of bone centers in hand and wrist of children with chronic nutritive failure. Effect of dietary supplements of reconstituted milk solids.** *Amer. J. Dis. Child.*, 1954, **87**, 429-439. [Dept. Nutrit. Metabol., Northwestern Univ., Chicago, Ill.]

Each of 82 children given a supplement was paired with a control who received no supplement. The supplement was equivalent in protein value to 6 qt. milk weekly for 20 months for 41 children aged 4 to 15 years and to 3 qt. weekly for 40 months for 41 children aged 1 year to 10 years 8 months. From the second group 19 children were arbitrarily selected to receive the equivalent of 12 qt. weekly for a further 6 months. X-ray examinations were made of 28 ossification centres in each child at the beginning and end of supplementation. All bone centres were retarded by chronic malnutrition. The centres which were least retarded made the greatest relative gains in response to the addition of milk to the diet. The mean maturation rate of all centres was directly related to the quantity of milk supplied.—F. C. Aitken.

4972

ABBIE, A. A. and ADEY, W. R. **Ossification in a Central Australian tribe.** *Human Biol.*, 1953, **25**, 265-278. [Dept. Anat., Univ. Adelaide, S. Australia.]

The results of X-ray photography of the wrist-hand and ankle-foot regions of infants, children and adolescents, 27 male and 31 female, mostly of the Ngalia tribe of Australian aborigines at the Yuendumu Settlement some 200 miles north-west of Alice Springs, are presented in tables, with 1 illustrative plate. The times of ossification fell within the normal European range but were generally nearer the earlier limit than the later. The aborigines showed the same tendency, greater in the female, towards suppression of the bones of the outer side of the foot as is found in Europe and there ascribed to civilisation, in particular, footwear.—W. M. Deans.

4973

BRYAN, A. H. and GREENBERG, B. G. **Methodology in the study of physical measurements of school children. 2. Sexual maturation—determination of immaturity points.** *Human Biol.*, 1952, **24**, 117-144. [Sch. Pub. Health, Univ. N. Carolina, Chapel Hill.]

Methods of analysis of quantal response are used to discover whether samples of boys or of girls differ significantly in their group mean age of sexual differentiation, in studies where observations are made only once on each child.

Data from routine medical examination of 101 girls and 86 boys showed the numbers of boys who were infantile in respect of genital development, pubic hair and axillary hair, respectively, and the numbers of girls infantile in respect of breast development, pubic hair, axillary hair and menarche, for each of 5 age groups from 9 years and over to 13 years and over. From the data, 30, 50 and 70 per cent. immaturity points were calculated for each characteristic, that is, ages at which it was estimated that these percentages of the population studied would be infantile. In computing the immaturity points, probit analysis, logit analysis, and Karber's method gave similar results. Karber's method is recommended as involving less computation than the others, and as being equally sound from a theoretical point of view for the limited data available.

In order to study the discriminatory power of the analyses, the data were divided into subgroups in a number of ways, according as the heights or weights of the children were above or below the averages for their ages. The results of these tests were satisfactorily in agreement with previous findings, showing that for girls the signs of maturity appear earlier in those who are taller or heavier at the ages studied than in those who are shorter or lighter. No such effect is found for boys, and it is suggested that the pubertal spurt in height and weight occurs later in boys than in girls, and would be most evident at ages beyond the range of the present data. As regards dis-

criminating power, the result showed that differences in 50 per cent. immaturity points of 0.8 to 1.0 year may be established from samples of girls numbering about 50.—I. McDonald.

4974

BERRY, W. T. C. and COWIN, P. J. **Conditions associated with the growth of boys, 1950-1.** *Brit. Med. J.*, 1954, i, 847-851. [Minist. Health, Savile Row, London, W.1.]

Although the nutrient intakes of children in the United Kingdom are considered adequate [at the time of the study] even in the lowest income group, well-marked differences of stature still exist between children of different social groups. Possible reasons are discussed and a preliminary investigation of the effect on growth of environmental conditions other than diet is described. The subjects, 1527 in all, were boys of 6, 10 and 14 years in the contrasted environments of Salford and Kingston-on-Thames and boys of 14 years in Bristol attending modern, grammar and public schools. Height (cm.), weight (kg.) and biacromial, bitrochanteric and chest measurements as a percentage of height are tabulated.

The Salford boys were shorter and lighter than the Kingston boys at all ages and at Bristol modern school boys were surpassed in both respects by grammar and they by public school boys. As was found by Weir (Abst. 2581, Vol. 23), the taller, heavier groups tended to be of slimmer build. Puberty, as judged from pubic hair, was delayed in Salford compared with Kingston, and in Bristol modern compared with Bristol grammar schools. There was a suggestion that pallor was associated with low weight, and thinness, judged by skinfold thickness, with low stature [full data not reproduced].

More detailed studies in Bristol on the effect of environment on weight are reported. (Height varied similarly, but in less degree.) Diets were classified as poor, average and good by asking the boys how much milk they drank and how often they had meat or fish, and fresh fruit. Mean weight increased progressively from poor to good diet. Weight also increased with standard of parental care, independently of diet, and among grammar, but not modern, school boys with social class (Registrar-General's classification). Boys who shared beds were lighter than boys of similar background who did not. The difference between boys from a housing estate and the centre of the city was not conclusive. No adverse effect of broken homes was found. Boys whose mothers went out to work were significantly heavier than boys whose mothers did not.

In the interpretation it is pointed out that some of the differences may reflect the environment of the past instead of the present. It is suggested

that "non-dietary factors cannot be ignored as a potential cause of checks to growth" and that they may act by affecting the appetite.

CLEMENTS, E. M. B. **Changes in the mean stature and weight of British children over the past seventy years.** *Brit. Med. J.*, 1953, ii, 897-902. [Dept. Anat., Univ. Birmingham.]

A survey is made of measurements of height and weight of British children, obtained in different urban centres over the past 70 years. It was found necessary to adjust the original results to allow for systematic differences in the methods of collection and classification. Where possible the data for each sex were separated into 3 groups according to social and economic background. The approximate dates of the measurements were 1880, 1905, 1920, 1940 and 1947, and the differences in mean height and weight over each of the 4 intervening periods are given for 5- to 7-, 8- to 10-, and 11- to 13-year-old boys and girls, in separate tables for each income group.

It was found that over the whole period there were significant increases, representing an acceleration in growth of about 18 months. The increases were greater in older than in younger children, and in the lower than in the upper income groups. The rate of increase appears to have been greatest in the inter-war years and to have been checked during both world wars.—I. McDonald.

NEWCOMER, E. O. and MEREDITH, H. V. **Eleven measures of body size on a 1950 sample of 15-year-old white schoolboys at Eugene, Oregon.** *Human Biol.*, 1951, 23, 24-40. [Sch. Health Phys. Educat., Univ. Oregon, Eugene.]

4977

CLEMENTS, E. M. B. **The age of children when growth in stature ceases.** *Arch. Dis. Childhood*, 1954, 29, 147-151. [Dept. Anat., Univ. Birmingham.]

From a statistical study of 4-monthly height measurements, without shoes, of 75 boys and 67 girls of the upper income group, made in the periods 1949-52 and 1945-52, respectively, it was concluded that the mean age when growth ceases in boys is 17 years 9.08 months \pm 1.87 months (S.D. 9.96 months), and in girls 16 years 2.71 months \pm 3.44 months (S.D. 13.62 months). In some, there was a plateau [incidence and placing not defined] followed by a second period of growth.

On the average, growth ceases some 9 or 10 months earlier than at the time of the British Association Report (1883); but it is not clear whether this is due to a general tendency for all

children to mature earlier, or to a selective change, e.g., to a reduction in the frequency of older children who are still growing.—W. M. Deans.

4978

THOMSON, J. **The influence of age on the Tuxford Index.** *Health Bull., Dept. Health for Scotland*, 1953, **11**, 64–65.

A number of children aged exactly 3, 4, 5 and 10 years were selected from numbers born at the Royal Infirmary, Edinburgh. The mean Tuxford Index for boys of the above ages was 939, 957, 975 and 1073, respectively, and for girls 943, 964, 990 and 1070. In neither sex was the difference between the means of the 3- and 4-year-old group and the 4- and 5-year-old group significant, but in both sexes the difference between the 3- and 5-year-old group and the 5- and 10-year-old group was significant. No particular stress is laid on these averages, since the numbers measured were small.—A. W. Boyne.

QUO, S. K. **Mathematical analysis of the growth of man, with special reference to Formosans.** *Human Biol.*, 1953, **25**, 333–358. [Dept. Hyg. Pub. Health, Coll. Med., Nat. Taiwan Univ., Taipei, Formosa.]

Weight change is taken as the best index of human growth, and records of weights and ages of about 87,000 male and 83,000 female Formosans from birth to 40 years, which were originally measured between 1938 and 1950, are examined. In the discussion of the data it is assumed that the comparisons between the mean weights of different age groups are equivalent to comparisons between the weights at different times of a single group of individuals followed up from birth.

When the age range was grouped as from birth to 9 months, 9 months to 5 years, 5 to 13 years and 13 years and upwards, equations of exponential type relating weight to age could be fitted. The constants of the equations for male and for female Formosans are given.

The data are discussed in relation to the functioning of the endocrine glands, with particular reference to changes after birth and at adolescence.

GRAY, M. J. and PLENTL, A. A. **The variations of the sodium space and the total exchangeable sodium during pregnancy.** *J. Clin. Invest.*, 1954, **33**, 347–353. [Dept. Obstet., Coll. Phys. Surg., Columbia Univ., N.Y.]

Sodium space and total exchangeable Na were estimated with ^{24}Na in 10 primigravidae, of whom one subsequently developed mild pre-eclampsia and 3 others excessive nausea and vomiting. In 6, pregnancy was entirely uncomplicated. All babies were normal. Several estimations were made on each patient.

The average Na space was 24.4 per cent. of bodyweight (range 19.3 to 29.5) and the total exchangeable Na was 39.3 m. equiv. per kg. bodyweight (range 31.9 to 49.5). There was no evidence of Na storage, the 6 normal patients

N.A. and R., October 1954

gaining an average of 510 m. equiv. during pregnancy and losing an average of 440 m. equiv. within a month *post partum*. The gains could be accounted for in the products of gestation and in the expanded maternal blood volume. "A possible explanation for the discrepancy between these data and those of others may be sought in the fact that . . . only exchangeable sodium has been determined while the classical balance studies consider the net gain in the sum of exchangeable and permanent sodium. One would have to assume that enormous amounts of sodium are stored in bone in a non-exchangeable form, and direct evidence to this effect does not exist."—A. M. Thomson.

FEKETE, S. **The significance of mucopolysaccharides in the pathogenesis of toxæmias of pregnancy.** *Acta med. hung.*, 1954, **5**, 293–308. [Szövevény St. Municip. Hosp., Budapest.] Russian summary.

Weighed pieces of skin and subcutaneous tissue, obtained at caesarean section and other operations, were placed in duplicate in measured quantities (5 or 10 ml.) of distilled water, 0.85 per cent. saline and 5 per cent. saline. Solutions were maintained at 4° to 8° C., to minimise decomposition. The tissues were weighed after drying with filter paper at the end of 24 hr., and the Cl, N and sugar contents of the surrounding fluids were estimated. The tissues were returned to their fluids for a further 48 hr., 1 ml. of a 0.1 per cent. solution of hyaluronidase being added to one tube of each pair. The weighing and analyses were then repeated, 1 ml. of inactivated (heat-treated) hyaluronidase solution being added to the control tubes immediately before the tissues were weighed. It was found that the tissues take up water and release most of it when treated with hyaluronidase. This effect of hyaluronidase was more marked in tissues obtained from women during the second half of pregnancy, and was specially marked when oedema was present. There was little difference in effect between tissues immersed in the different solutions. In some cases, marked uptake and release of NaCl from tissue samples in 5 per cent. NaCl solution was noted. Similar but increased effects were noted when the experiments were repeated with samples of umbilical cord tissue. Samples of uterine muscle took up water and salt but did not release it on treatment with hyaluronidase. It is postulated that the mucopolysaccharide content of skin and subcutaneous tissue increases in pregnancy and especially in toxæmia. The effects observed "are attributed to the depolymerisation by hyaluronidase of hexosamine-containing mucopolysaccharides, whereupon they release salt and water".

A. M. Thomson.

GABRAWY, B. and KAMAL, I. **Histidine excretion in normal and abnormal pregnancy.** *J. Obstet. Gynaecol. Brit. Empire*, 1954, **61**, 186–191. [Dept. Physiol., Med. Fac., Kasr-el-Aini, Cairo.]

Histidine was estimated by the method of Kapeller-Adler (*Quart. J. Exp. Physiol.*, 1949, **35**, 145) modified for use with urine. No significant difference was found in the excretion of histidine in men and women, pregnant or non-pregnant; patients with severe toxæmia of pregnancy excreted about the same amount as normal subjects on a low-protein diet. There appears to be no abnormality of histidine metabolism in pregnancy normal or abnormal, and earlier results suggesting such an abnormality are attributed to faulty methods of estimation.—I. Leitch.

4990

STARY, Z., EREZ, N., BODUR, H., ANHEGGER-LISIE, S. G. and ÇEPELOĞLU, R. **Über einige die spontane Frühgeburt begleitende Veränderungen der Proteine des mütterlichen Blutes. [Some changes in maternal blood proteins accompanying spontaneous premature labour.]** *Arch. Gynäkol.*, 1954, **184**, 330–336. [2. Frauenklin., Univ. Istanbul.]

During pregnancy there are 2 phases in the increase of serum protein-bound polysaccharides. In the 8th month, there begins an increase in the polysaccharides of the albumin fraction, which continues until shortly before the birth. Immediately before the birth there is a change in polysaccharide metabolism, and the excess of the albumin polysaccharides is replaced by an increase in the polysaccharides of the globulin fraction. In spontaneous premature labour this increase of the globulin-bound polysaccharides sets in prematurely and reaches a much higher level than with a normal birth.—M. B. Richards.

4991

WIEHL, D. G. and TOMPKINS, W. T. **Size of babies of obese mothers receiving nutrient supplements.** *Milbank Mem. Fund Quarterly*, 1954, **32**, 125–140. [Nutrit. Res. Clin., Pennsylvania Hosp. (Philadelphia Lying-in Hosp.).]

A total of 235 women who were obese at the beginning of pregnancy were given instructions for a restricted diet and in 4 comparable groups were given a vitamin or protein supplement, or both, or none. Compared with a group of 467 women of standard weight at the beginning of pregnancy the group of 235 obese women contained a larger percentage delivered late and a smaller percentage delivered early. Babies of obese women were on the average heavier than those of women of

standard weight. This was so even when comparison was restricted to babies born within 7 days of expected date of delivery. The babies of obese women were also longer. No correlation was found between birthweight and maternal weight gain during pregnancy.

In the group receiving both vitamin and protein supplements the percentage of women delivered within 1 week of the expected time was significantly higher than in the other groups. This was due chiefly to a significantly smaller percentage of early deliveries in the group given vitamin and protein supplements. Differences in weight of babies and in length of babies born within 1 week of expected delivery time in the 4 groups were not significantly different.—F. C. Aitken.

4992

GLASS, S. J. and LAZARUS, M. L. **Improved fertility and prevention of abortion after nutritional hormonal therapy.** *J. Amer. Med. Assoc.*, 1954, **154**, 908-910. [Fertility Clin., Cedars of Lebanon Hosp., Los Angeles, Calif.]

Clinical examinations and liver function tests were made on 22 men and 50 women attending a fertility clinic. All were given a diet providing optimum energy intake (designed to reduce weight when necessary), protein content of 1.5 to 2 g. per kg. bodyweight, 25,000 to 50,000 units vitamin A, foods rich in vitamin B complex, and 30 to 60 g. wheat germ daily. After 30 to 60 days on this diet treatment with sex hormones was begun.

Fertility with resulting pregnancy was restored to 19 of 34 nulliparous women and to 4 of 6 multiparae, but 4 of these 23 aborted. Of 10 women who had had 2 or more abortions, 8 had normal babies. Of the 22 sterile men, 15 had improved spermatogenesis and 10 of their wives became pregnant; one aborted. These results were achieved in from 4 to 22 months. Most of the patients showed improvement in general health. Results were much better than those obtained from hormonal treatment alone.—D. Duncan.

BOYNE, A. W., CHALMERS, M. I. and CUTHBERTSON, D. P. Gleichgewicht und Verteilung des Stickstoffs bei der trächtigen und laktierenden Ratte. [Nitrogen equilibrium and distribution in the pregnant and lactating rat.] *Hoppe-Seyler's Ztschr.*, 1953, **295**, 424-435. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The distribution of N in the tissues of pregnant and lactating rats was studied during the first and fifth reproductive cycles. An investigation of N equilibrium was made in the first reproductive cycle during the period from conception to the 16th day of lactation. No evidence was obtained of N storage in non-reproductive maternal tissues taken together, in either young or old pregnant rats. The increase of total N in the whole organism of pregnant rats is the result of the increase of total N in the reproductive tissues. In all cases the liver of pregnant and lactating rats showed an increase in weight and total N content over those of the controls. In the lactating rat the emptied and washed intestine showed, on the 16th day, a significant increase in weight and total N content. The investigations on N balance confirmed the results obtained from analysis of the tissues.

RAULIN, J. Rôle de la nature des lipides alimentaires dans l'action des surcharges de cholestérol sur le comportement du rat blanc. [Role of dietary lipids in the action of excess cholesterol on reproduction in the white rat.] *Arch. Sci. physiol.*, 1954, **8**, 1-26. [Lab. Biochim. Nutrit., C.N.R.S., Bellevue.]

Seven groups of rats were fed on diets containing (1) no fat, (2) 10 per cent. margarine and 5 per cent. lard, (3) 5 per cent. lard and 15 per cent. sunflower seed oil, (4) 15 per cent. margarine, (5) 20 per cent. sunflower seed oil (6) 7 per cent. margarine and 8 per cent. sunflower seed oil fatty acids and (7) 15 per cent. sunflower seed oil fatty acids. The remainder of the diet was casein, sucrose, cellulose, salt mixture and vitamins. Other groups of rats were given the same diets, but in addition received amorphous cholesterol, in amounts up to 3 per cent. of the diet.

As judged by the numbers and weights of offspring produced (dead and alive), cholesterol and the dietary fat had an influence on reproduction. In diets containing lard, cholesterol increased the average number per litter and the average weight of offspring. Reproductive performance was impaired by the highly unsaturated sunflower seed oil, more so when cholesterol also was given. When the fatty acids of sunflower seed oil and cholesterol were included in the diet, nearly all the foetuses died *in utero*; parturition occurred in the

N.A. and R., October 1954

animals given the fatty acids alone, though several of the young were born dead.

The results are discussed in relation to a possible increase of formation of sex hormones associated with cholesterol and highly unsaturated fatty acids.

BONADONNA, T., BERG, E., OLGATI, L. and POZZI, G. C. Osservazioni preliminari sul contenuto in fruttosio, sulla fruttolisi dello sperma di "Bos Taurus" e sulle correlazioni con la fecondità. (Nota preventiva.) [Preliminary studies of fructose content of and fructolysis by the semen of *Bos taurus* and their relations to fertility. Preliminary note.] *Zootec. Vet.*, 1954, 9, 70-82. [Ist. Sper. Ital. L. Spallanzani, Milan.] English summary.

The fructose content of the semen of bulls of different ages, breeds and strains was estimated 1, 2 and 3 hr. after collection. There was great variation in the initial content even between different collections from the same bull. There was no correlation between the initial content and age. The higher the fertility of the bull as shown by records, the higher was the initial fructose content. High fructose contents were related also to greater libido. The rate of disappearance of fructose after collection was constant for individuals when the number of live spermatozoa in the semen was taken into account.—T. D. Bell.

HYTTEN, F. E. Clinical and chemical studies in human lactation. 6. The functional capacity of the breast. *Brit. Med. J.*, 1954, i, 912-915. [Dept. Midwifery, Univ. Aberdeen.]

Measurement of breast size by water displacement is described. In a study of 86 primiparae and 23 multiparae there was a significant positive correlation between breast size and output of milk on the seventh day of lactation. Breast size was not related to milk composition. Breast enlargement during pregnancy was studied in 9 primiparae and 2 multiparae. In the primiparae there was a high positive correlation between breast enlargement during pregnancy and output of milk on the seventh day. There was no relation between initial size and subsequent enlargement. (For earlier parts see Abst. 2850, Vol. 24.)—F. C. Aitken.

CAMPBELL, B. and PETERSEN, W. E. Milk "let-down" and the orgasm in the human female. *Human Biol.*, 1953, 25, 165-168. [Dept. Anat., Univ. Minnesota.]

Five instances were studied in which milk let-down in women occurred during sexual intercourse. The suggestion is advanced that orgasm in the human female consists in a neurohumoral reaction of smooth muscle organs, often accompanied by a concurrent vestige of a male behaviour pattern involving contraction of the homologues of the muscles of ejaculation. The success of the reproductive act may be related to the first of these phenomena, but not to the second.—D. Duncan.

BARTLETT, S., BURT, A. W. A., FOLLEY, S. J. and ROWLAND, S. J. Relative galactopoietic effects of 3:5:3'-triiodo-L-thyronine and L-thyroxine in lactating cows. *J. Endocrinol.*, 1954, 10, 193-201. [Nat. Inst. Res. Dairying, Univ. Reading.]

Oral doses of 16, 32 and 64 mg. 3:5:3'-triiodo-L-thyronine (T.I.T.) and 75 mg. L-thyroxine were compared in their effect on the milk yield and composition and the heart rate of dairy cows.

Milk yield was increased by all treatments, but the response to T.I.T. was far less, even at the highest level, than to L-thyroxine. L-Thyroxine increased butterfat percentage and reduced the concentration of alkaline phosphatase, but T.I.T. had no effect. No treatment affected the percentage of solids-not-fat. Heart rate gradually increased during L-thyroxine treatment. After 64 mg. T.I.T. it increased immediately and then slowly declined to normal; after smaller doses the effect was slight.

L-Thyroxine or T.I.T., 5 mg. daily, in single subcutaneous injections increased yield, butterfat and solids-not-fat percentages and heart rate, and reduced alkaline phosphatase. The response to T.I.T. was slightly greater. When the dose was given as 2.5 mg. twice daily the results were the same.—T. D. Bell.

COTES, P. M. and CROSS, B. A. The influence of suckling on food intake and growth of adult female rats. *J. Endocrinol.*, 1954, 10, 363-367. [Dept. Biochem., Univ. Cambridge.]

Growth increments and food intake in the first 14 days *post partum* were greater, both in normally

lactating rats and in suckled rats with galactophores cut to prevent milk withdrawal, than in unsuckled controls. The increased food intake of the rats with galactophores cut could not have been required for milk production, for test weighings showed that litters were unable to obtain milk from these rats. It seems, therefore, that the suckling stimulus, rather than the metabolic condition associated with milk secretion, is the important cause of increased food intake and extra growth of suckled animals. Daily injections of 3 I.U. prolactin in non-suckled rats did not reproduce the changes in bodyweight or food intake.—M. B. Richards.

REPRODUCTION: BIRDS

5007

HAYS, F. A. **Artificial light for activating males and females to higher fertility.** *Poultry Sci.*, 1954, **33**, 321-327. [Massachusetts Agric. Exp. Stat., Amherst.]

Rhode Island Reds bred for high fecundity and housed at 8 to 10 breeding females per pen were used. Eggs were saved for a 6-week period in early February and March and subsequently hatched. The artificial lighting gave an intensity of 3 foot-candles at floor level and was switched on at 4 a.m. for 4 hr. to give light before natural

daylight. Control pens with natural daylight only were run concurrently. The experiments extended over 5 years.

All-night lights for 30 days from 1 January improved the fertility of cocks penned with pullets as the season advanced. Morning lights for 60 days gave higher fertility than in controls but produced no significant increase as the season advanced. The fertility of cockerels mated to old hens was not stimulated by all-night lights for 60 days; that of old males mated to pullets significantly declined; all-night lights for 30 days raised fertility in similar matings. Morning lights for 60 days decreased the fertility of cockerels mated to old hens, but had no effect on old males similarly mated. All-night lights for 30 days for males followed by all-night lights on male and female in the breeding pen gave a progressive decline in fertility through the hatching season. Morning lights in a similar set-up significantly stimulated both males and females to higher fertility.—M. J. Head.

SENESCENCE

5008

RENBOURN, E. T. and ELLISON, J. M. **Some blood changes in old age. A clinical and statistical study.** *Human Biol.*, 1952, **24**, 57-86.

Data were collected over a number of years for 140 people of 60 to 104 years of age. All were clinically healthy and none was bedridden. A subjective assessment of fitness for age was based on several weeks of observation, and was followed by blood tests to obtain values for haematocrit, erythrocyte sedimentation rate, red cell fragility, blood urea, blood chloride, blood cholesterol and blood pressure.

The data were analysed to test for differences between men and women, changes in mean values and variabilities with ageing and as compared with younger groups, differences corresponding to the different fitness assessments, and relations between measurements.

There is a review of the literature.

SILBERBERG, M. and SILBERBERG, R. **Factors modifying the lifespan of mice.** *Amer. J. Physiol.*, 1954, **177**, 23-26. [Snodgrass Lab., St. Louis City Hosp. Div., Mo.]

The mice were 205 males and 130 virgin females of strain C57BL and 128 males of strain DBA, both closely inbred strains. Some received the

N.A. and R., October 1954

stock Purina laboratory chow, the rest the same diet with 24 per cent. added lard.

Males of strain C57 reached their maximum mean weight at 15 months of age on stock diet, but on high-fat diet they continued to put on weight until 22 months old, when their mean weight was 25 per cent. greater than that of mice on stock diet. In males of strain DBA the maximum mean weight was 24 g. on both diets, but was attained at 17 months on stock diet and at 11 months on high-fat diet. The deviations from the mean were much greater in C57 mice on high-fat diet than in others.

The high-fat diet shortened the lives of C57 males by 16 per cent. and of DBA males by 9 per cent., but did not affect survival of females. The females showed higher mortality at all ages than the males. The males of strain C57 lived longer than those of strain DBA, but the high-fat diet was more harmful to the former. While the greatest shortening of life was on average associated with the most conspicuous increase in body-weight, there was no consistent correlation between overweight and length of life in individuals.

SCHNEIDER, J. and MONTÉZIN, G. *Pl. berghei* et lait. Absence d'action du régime lacté chez la souris. [*Plasmodium berghei* and milk. Absence of effect of a milk diet in the mouse.] *Bull. Soc. Pathol. exot.*, 1953, **46**, 947-952. [Lab. Chim. Thérap., Inst. Pasteur, Paris.]

Of mice weighing about 20 g., 13 were maintained on a diet of cow's milk and 6 on a normal diet; on the 3rd or 5th day of the milk diet all were infected with 25 million organisms of *P. berghei*. All the animals except one in each group died. Those on the milk diet survived somewhat longer, but there was little difference. The results did not confirm those of Maegraith *et al.* (Abst. 4848, Vol. 23) with the rat, but the mouse is more sensitive than the rat to *P. berghei*, the infection was much heavier and the diet was of milk without addition of B vitamins.

SIROTNAK, F. M., DOETSCH, R. N., ROBINSON, R. Q. and SHAW, J. C. Aspartate dissimilation reactions of rumen bacteria. *J. Dairy Sci.*,

Vol. 24, No. 4

1954, **37**, 531-537. [Dept. Bacteriol., Univ. Maryland, College Park.]

On incubation with washed cell suspensions and cell-free extracts of rumen contents succinate gave a total CO₂ production plus propionate yield similar to those of aspartate, but without NH₃ production. When malonate was used to inhibit CO₂ output without the inhibition of malate decarboxylase, NH₃ production exceeded CO₂ production.

On incubation with aspartate, after 5 hr. the fatty acid was mainly propionate, but thereafter this decreased and acetate increased. Butyrate was detected after the acetate concentration increased to about 40 per cent. of the total fatty acid. The yields of total fatty acids were high.

Alpha- and β-alanine produced no CO₂ or NH₃ with cell-free preparations and no fatty acid with washed suspensions of rumen organisms. Primary decarboxylation of aspartate was therefore unlikely. Oxaloacetate gave a similar result. Malate produced more CO₂ than aspartate, and acetate was the main fatty acid after incubation for 5 hr. Fumarate gave CO₂, but fatty acids did not accumulate. From these results and from the evidence of malonate inhibition it is concluded that these are unlikely to be intermediates in the dissimilation of aspartate.

Pyruvate gave a poor yield of CO₂ with the washed cell suspensions, and some unidentified gas. It gave rise mainly to acetate, with significant amounts of butyrate and propionate. Lactate produced little CO₂ and no acid.

Aspartate is thought to be degraded via succinate to propionate and then to acetate and butyrate. It is suggested that the dicarboxylic acids tested are not interconvertible in the rumen.

WILSON, M. K. and BRIGGS, C. A. E. The normal flora of the bovine rumen. 1. Bacteriological methods for quantitative studies. *Vet. Rec.*,

1954, **66**, 187-188. [Nat. Inst. Res. Dairying, Shinfield, Reading.]

Counts of viable bacteria in the rumen contents were made in a reinforced clostridial medium buffered with NaHCO_3 and saturated with CO_2 . No improvement was found when this medium was enriched with horse serum, Tween 80 or cellobiose, but the addition of Tween 80 to dilution blanks resulted in consistent small improvements in counts. This may be due to more complete separation of bacteria from aggregations and from food particles by the physical properties of Tween 80. No great disparity in final count was found between incubation temperatures of 37°C . and 39°C . Ten days was the greatest time required for any bacterium which grew in this medium.

Samples were taken from adult cows with large fistulae. Tenfold serial dilutions made directly into the culture medium gave counts of 10^{10} and 10^{11} organisms per g. rumen contents. The organisms were chiefly Gram-positive cocci and rods of varied morphology. Gram-negative organisms rarely exceeded 10^6 to 10^7 . From this it is claimed that a considerable proportion of the viable population was cultivated *in vitro*. Seven minutes was the maximum time allowed between sampling and culturing. Replicate samples from 5 sites in the rumen, rumen liquor and solid material showed differences of up to a thousandfold in count, as did those from cow to cow, from hour to hour or day to day when 3 cows were sampled hourly for 25 hr. Variations due to diet were also as much as a thousandfold. The authors regard this as of particular importance, since other workers have considered smaller changes indicative of significant major alteration in the flora.

HUHTANEN, C. N., SAUNDERS, R. K. and GALL, L. S. **Fibre digestion using the miniature artificial rumen.** *J. Dairy Sci.*, 1954, **37**, 328-335. [Nat. Dairy Res. Labs., Oakdale, Long Island, N.Y.]

Miniature artificial rumens consisting of dialysis tubing suspended in screw-cap jars and maintained in a synthetic saliva solution were used for studies of fibre digestion during 24-hr. periods. Fibre was estimated colorimetrically.

With 20 samples of alfalfa hay, fibre digestion was 47 ± 4 per cent. The effects of penicillin, aureomycin, bacitracin and terramycin on fibre digestion were studied with different concentrations of the antibiotics. All inhibited fibre breakdown to some extent and terramycin completely suppressed it even at low concentrations. The addition of starch and lactose to roughage depressed fibre digestion.

The technique did not call for constant neutralisation of the medium and was thus an improvement on Louw's artificial rumen.—D. M. Walker.

5017

BRIGGS, C. A. E., WILLINGALE, J. M., BRAUDE, R. and MITCHELL, K. G. **The normal intestinal flora of the pig. 1. Bacteriological methods for quantitative studies.** *Vet. Rec.*, 1954, **66**, 241-242. [Dept. Bacteriol., Nat. Inst. Res. Dairying, Shinfield, Reading.]

To study the conditions influencing counts of viable bacteria in the faeces of pigs, counts were made by the dilution technique using 3 media, one for the coli-aerogenes group, a clostridial medium and one for general counts.

Intra-sample variations were insignificant. Variations in counts due to delay in culturing of the faecal bacteria were not consistently found, but it is suggested that cultures should be set up as early as possible. Total counts of faecal bacteria showed that the numbers for pigs on a normal diet generally fell between 1.0×10^8 and 9.9×10^9 per g. wet weight. Total counts of faecal bacteria of pigs on two other diets fell within these limits and it is not thought that the quality and quantity of a ration influence the numbers of organisms in the intestinal flora, though variations in bacterial types may occur.

A comparison of counts and dry matter contents of faecal and caecal materials was made. The ratio of faecal to caecal dry weights, which was 1.9, was used to bring the counts of caecal bacteria nearer those of faecal bacteria. High dilution of faecal bacteria resulted in the growth of lactobacilli and streptococci. Coli-aerogenes bacteria were fewer than lactobacilli and streptococci as shown by growth in MacConkey's broth; and low dilutions plated direct resulted in the growth of micrococci, bacilli, *Pseudomonas* and moulds.

5018

COOK, F. D., BLAKELY, R. M., MACGREGOR, H. I. and ANDERSON, R. W. **The effect of antibiotics on the intestinal microflora of turkey poults.** *Poultry Sci.*, 1954, **33**, 38-40. [Dominion Exp. Stat., Swift Current, Sask.]

Day-old turkey poults were kept in heated brooders and given a mixed practical ration containing animal protein, with or without 9 p.p.m. procaine penicillin; 3 birds from each group were killed each week and the microflora of the gizzard, duodenum, small intestine, caeca and large intestine was examined.

The number of lactobacilli in the gizzard was low in both groups but rose steadily to the 4th week of age and was unaffected by the drug. Penicillin suppressed lactobacilli in the duodenum during the first 3 weeks but thereafter the numbers

in each group were similar, which suggested the development of resistant strains in the drug-fed group. Counts in the small intestine over the 5-week period clearly showed that penicillin consistently reduced the lactobacillus population. The drug had no effect on the number of lactobacilli in the caeca; in the large intestine the picture was similar to that in the duodenum. Coliform bacteria counts were made only in the large and small intestines and in the caeca; penicillin had no effect on the count in the last but raised the count 10 to 1000 times in each of the intestinal regions.

WAINFAN, E., HENKIN, G., RITTENBERG, S. C. and MARX, W. Metabolism of cholesterol by intestinal bacteria *in vitro*. *J. Biol. Chem.*, 1954, **207**, 843-849. [Dept. Biochem., Sch. Med., Univ. S. California, Los Angeles.]

Homogenates of intestinal contents and faeces were prepared from rats which had been fed for about a year on a diet containing 1.5 per cent. cholesterol and 0.5 per cent. ox bile. The homogenates contained considerable quantities of cholesterol, which decreased on incubation. In control homogenates treated with alcohol or autoclaved no decrease in cholesterol was found after incubation.

Fifteen strains of cholesterol-metabolising bacteria were isolated in pure culture. The two most

active strains were *Aerobacter aerogenes* and *Pseudomonas jaegeri*. Addition of cholesterol to resting cell suspensions of these strains increased oxygen uptake and the cholesterol content of the flasks decreased with time by as much as 80 per cent. Addition of nicotinamide to resting cell suspensions of *A. aerogenes* increased the oxygen uptake when cholesterol was present, but no such effect was noted with dried cells which had been stored in the cold for several days, although these cells could still metabolise cholesterol. 2:4-Dinitrophenol increased the rate of cholesterol oxidation by both *A. aerogenes* and *P. jaegeri*. Rate of oxidation was related also to the number of viable cells in suspensions.—M. J. Dobson.

5024

GYLLENBERG, H., ROSSANDER, M. and ROINE, P. On the growth-inhibition of *Lactobacillus bifidus* by certain fatty acids. *Acta chem. scand.*, 1954, **8**, 133-134. [Dept. Nutrit. Chem., Univ. Helsinki.]

Growth of strains of *Lactobacillus bifidus* isolated from the faeces of breast-fed infants was inhibited *in vitro* by some fatty acids. Propionic and butyric acids had no effect, caproic acid was slightly inhibitory, and the inhibitory effect increased with the length of the carbon chain up to lauric acid, but with greater chain lengths toxicity declined again. Palmitic, stearic and oleic acids had some effect, but ricinoleic was about 5 times as effective as oleic acid.

Egg albumin, casein and blood albumin partly overcame the inhibitory effect of fatty acids, gelatine was less effective, and trypsin, pepsin or yeast extract had little or no effect.

Both human and cow's milk had detoxifying effects which were abolished by tryptic digestion.

GRILLO, M. A. Sul metabolismo della treonina nel *Saccharomyces cerevisiae*. [Threonine metabolism in *Saccharomyces cerevisiae*.] *Arch. Sci. biol., Bologna*, 1954, **38**, 145-154. [Ist. Chim. Biol., Univ. Turin.]

Extract of yeast decomposes threonine, with formation of acetaldehyde. In the process no oxidation and no formation of ammonia or α -ketobutyric acid is found. *d*- and *l*-Threonine are attacked with the same velocity. The process is activated by adenosine-5-phosphate, glutathione

and pyridoxal phosphate. If the yeast extract is previously treated with norite A less acetaldehyde is formed: the activity is restored by glutathione. Glutathione and pyridoxal phosphate, but not adenosine-5-phosphate, restore the activity to yeast inactivated by long dialysis. Biotin has no effect on the formation of acetaldehyde from threonine.—M. B. Richards.

KAGAN, M. J. O vliyanii sostava pishchi na regeneratsionnyi protsess skeletnoi muskulatry u myshei. [The influence of food composition on the process of regeneration of skeletal musculature in mice.] *Dokl. Akad. Nauk S.S.S.R.*, 1953, **91**, 683-686. [Leningrad Med. Inst.]

Leg muscles of mice were injured by cutting and the effect of the protein content of the diet on regenerative processes was studied. Five groups of mice received: (1) a natural balanced diet with protein content 18 per cent., (2) a synthetic balanced diet, (3) a restricted diet with 12 per cent. protein, (4) a low-protein, high-carbohydrate diet, 1.5 per cent. protein, (5) a high-protein, low-carbohydrate diet, 36 per cent. protein.

The animals were operated on 20 days after they had been on these diets. In groups 1 and 2 tissue breakdown terminated after 3½ days, and in groups 5, 4 and 3 after 4, 6 and 7 days, respectively. Regenerative processes began in groups 1 and 2 on the second day, but in group 3 not till the 6th day. Restoration of connective tissue was slower in groups 3 and 4 than in 1 and 2. In group 1 the wound was covered with disoriented muscle fibres, between which layers of connective tissue were formed. Wounds of group 3 animals were covered with atrophied muscle fibres of smaller diameter. Not only protein deficiency, but also excess, affects regeneration.—W. Hughes.

Male albino rats numbering 30, of average initial weight 127.2 g., were given a necrogenic diet (Abst. 4940, Vol. 20) and, where possible, bromosulphalein tests of their liver function were made. Nine died after having had the diet for between 27 and 58 days and before tests were made; all had hepatic necrosis. The 21 animals tested had had the diet for between 37 and 64 days and showed some impairment, their retentions of the dye ranging from 8.72 to 100 per cent. compared with 5.43 per cent. for normal control rats. The severity of the damage could not be correlated with the length of time on the diet. Nine more rats died between 2 and 24 days after the tests and showed hepatic necrosis at postmortem examination. Second tests were made between 36

N.A. and R., October 1954

and 38 days after the first on the 12 survivors and it was apparent that, in most, the degree of liver damage increased with the passing of time. This functional liver damage could occur even when morphological changes were absent or very slight. It is concluded that dietary hepatic necrosis is an acute manifestation of a chronic deficiency state.

M. B. Richards.

KAMRIN, B. B. **The effects of a high carbohydrate diet on the teeth of parabiosed albino rats.** *J. Dent. Res.*, 1954, **33**, 175-180. [Dept. Anat., Coll. Med., State Univ. New York, Brooklyn.]

A balanced non-cariogenic diet (Big Red Dog Pellets) containing 44 per cent. carbohydrate (manufacturers' analysis) was ground to pass a 30-mesh screen and powdered dextrose was added in equal volume, raising the carbohydrate content to 72 per cent. Ten pairs of parabiosed littermate Wistar rats were given the ground balanced diet, 7 pairs and 20 single rats the high-carbohydrate diet, all to appetite, from weaning to 120 days, when the rats were killed and the teeth were examined by probe under the microscope.

Addition of dextrose produced caries in both single rats and parabiosed rats. The effect was more marked in the latter, and the pattern and incidence in the 2 parabionts were almost identical; it is suggested that this may be useful in research on caries.—W. M. Deans.

5035

MUHLER, J. C. **Importance of type of diet during the suckling period on the incidence of experimental dental caries in rats.** *J. Dent. Res.*, 1954, **33**, 245-252. [Dept. Chem., Indiana Univ., Bloomington.]

Continuation of previous work (Abst. 5468, Vol. 20; 3936, Vol. 21) into the second generation of rats showed that the strain difference previously reported disappeared when both strains had a soft non-cariogenic diet from birth to 30 days, *i.e.*, before they were put on the cariogenic diet of coarse maize, and such rats eventually had less caries than those on the coarse maize diet from birth, from which it is concluded that newly erupted teeth are particularly susceptible to the effects of a cariogenic diet.

Stannous fluoride was again much more effective than sodium fluoride or stannous chloride in reducing the number of carious lesions, but in most groups the supplements were less effective in the second generation than in the first.—W. M. Deans.

5036

LARRIVEE, G. P. and ELVEHJEM, C. A. **Studies on the nutritional requirements of chinchillas.** *J. Nutrition*, 1954, **52**, 427-436. [Dept.

Vol. 24, No. 4

Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

The chinchillas numbered 67, were aged 2 to 9 months and appeared healthy. Conditions of housing are described. Synthetic diets with sucrose 37, vitamin-free casein 30, cottonseed oil and salt mixture each 4, vitamin mixture 2, potassium acetate 2.5, magnesium oxide 0.5 and cellulose or gum arabic 20 per cent. were prepared. The vitamin mixture contained neither vitamin C nor vitamin B₁₂. These diets were modified by reducing the amounts of K and Mg.

The variation in the roughage and in the K and Mg contents had no adverse effect, but from the nature of the faeces the cellulose diet was thought to be physiologically the better. The chinchilla differs from the guineapig in not requiring vitamin C.—D. Harvey.

5037

ORLAND, F. J., BLAYNEY, J. R., HARRISON, R. W., REYNIERS, J. A., TREXLER, P. C., WAGNER, M., GORDON, H. A. and LUCKEY, T. D. **Use of the germfree animal technic in the study of experimental dental caries. 1. Basic observations on rats reared free of all microorganisms.** *J. Dent. Res.*, 1954, **33**, 147-174. [Walter G. Zoller Mem. Dent. Clin., Chicago, Ill.]

The experimental animals were germ-free white rats from the Lobund Institute, Notre Dame. One group of 13, obtained by caesarean section, were hand-fed to weaning and kept in wire-bottomed cages, with 5 per cent. sucrose solution to drink; another group of 9, born naturally, were suckled by germ-free mother rats and bedded on wood shavings, with plain water to drink; both groups were housed in germ-free units (illustrated). Control groups of ordinary laboratory rats were in similar cages with similar beverages. All were fed from weaning on a diet of casein 20, ground polished rice 60, maize starch 0.5, cellophane spangles 3, fat 5, yeast extract 2, liver powder 2 and maize oil 1.6 per cent., fluorine-free salts 5 and vitamins. The diet contained 2.12 p.p.m. F and the sucrose solution 0.58. After from 137 to 256 days weights and skull and femur measurements were noted, the rats were killed and all molars were sectioned and examined by microscope and evaluated for caries in several different ways. A number of photomicrographs are reproduced.

The germ-free animals were smaller and lighter than the others, but growth and health were satisfactory. Their teeth were normally developed and showed normal wear. They seemed much cleaner than those of ordinary rats, and not a vestige of caries was found, even where traumatic fracture had occurred. All but one of the ordinary rats had caries; the average incidence was 4.8 carious molars per rat for those on wire floors with sucrose

solution and 3.2 for those on wood shavings and plain water. It was concluded that the rat does not develop caries in the absence of micro-organisms.

SUBRAHMANYAN, V., NATARAJAN, C. P., BHATIA, D. S., DESIKACHAR, H. S. R. and SANKARAN, A. N. **Utilization of *Agave* as an article of food.** *Bull. Central Food Technol. Res. Inst. Mysore*, 1953, **3**, 63-66.

Agave as the sole source of carbohydrate in a synthetic diet did not support growth of rats. Added as a non-leafy vegetable to a rice diet it produced better growth than the Knol-Khol which it replaced. The value of *Agave* was due mainly to its high Ca content.

It was concluded that *Agave* is a useful vegetable, but its use alone is not to be recommended even in an emergency.—P. C. Jowsey.

5039

BELL, J. M., GRAHAM, V. E., GIBSON, D. L. and LAWTON, W. C. **Increasing the food value of whey by yeast fermentation. 4. Feeding trials with mice.** *Canad. J. Technol.*, 1954, **32**, 55-59. [Dept. Dairy Sci., Univ. Saskatchewan, Saskatoon.]

Fermented whey powder was prepared as previously described (Abst. 4013, Vol. 23). It contained: water 5.3, protein 38.5, fat 12.1, Ca 2.5 and P 2.2 per cent., vitamin B₁ 3.6 mg. and riboflavin 21.3 mg. per lb. Weanling mice were given one of 2 basal diets containing: (1) wheat 66.0, oats 30.5 and minerals 3.5 parts; (2) maize starch 70, sucrose 3, minerals 4, cellulose 7, vitamin-free casein 13, crisco 3 and monosodium glutamate 0.25. Alternative B vitamin supplements were 2 per cent. dried brewer's yeast and 2 per cent. yeast-whey. Four protein supplements were yeast-whey alone or with methionine, dried skimmed milk or soya bean meal plus fishmeal plus alfalfa meal, to increase the total protein of the rations to 18 per cent. Food and water were allowed to appetite for 14 days.

With the grain diet, yeast-whey performed as well as any other protein supplement tested and B vitamins were adequate. Vitamin and methionine supplements had no effect. With the synthetic diet growth was significantly less with the yeast-whey as protein supplement than with skimmed milk, but when methionine was added to yeast-whey, growth was the same in the 2 groups. B vitamin supplements were without effect. Growth was poor when the soya-fish-alfalfa supplement was given alone, but addition of dried brewer's yeast produced good growth. Substitution of yeast-whey for brewer's yeast with this

protein supplement did not give good growth. It was considered likely that vitamin B₁ was lacking in yeast-whey.—P. C. Jowsey.

KRASOVSKAYA, S. A. O rastitel'nykh kormakh russkikh vykhukholei. [**The plant food of Russian muskrats.**] *Zool. Zh.*, 1953, **32**, 534-538. [Khopersk. Gosud. Zapovednik.]

It has been shown that muskrats eat the following plants: *Scirpus lacustris*, *Sparganium ramosum*, *Typha latifolia*, *T. angustifolia*, *Alisma plantago-aquatica*, *Symphytum officinale*. They eat *Nymphaea candida* rarely, but they eat the seeds readily; *Nuphar luteum* is not often eaten, nor does *Stratiotes aloides* constitute regular food for them. A list is given of plants which muskrats would not eat at all.—W. Hughes.

5041

WEIMAR, V. **Macrocytic anemia and leucocytosis of guinea pigs with muscular stiffness disease.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 488-491. [Dept. Zool., Oregon State Coll., Corvallis.]

Deficiency of the anti-stiffness factor produced anaemia, mild to severe, in guineapigs. There was macrocytosis, with decreases in the red cell count and in Hb per cell. Diminution in the number of young red cells occurred as early as after 3 to 10 weeks, and high sedimentation rates after 2 to 6 weeks of deprivation. There was a marked rise in the white cell count, but this usually was not evident until 3 to 5 months. The white cell differential count indicated granulocytosis. In deficient males the Kurloff type of cell disappeared completely.—M. B. Richards.

DE, N. K. **The alleged toxicity of Indian pulses.** *Indian J. Med. Res.*, 1953, **41**, 359-365. [Nutrit. Res. Labs., Indian Council Med. Res., Coonoor, S. India.]

The liver and kidney damage reported by Pal and Bose (Abst. 481, Vol. 14) in rats given diets high in pulses could not be produced, although mortality was high and many survivors suffered from paresis.

Addition of Ca and P to the high-pulse diet corrected deficiency of these elements, shown by chemical analysis; rats given the supplemented diet grew well and showed no sign of paresis.

N.A. and R., October 1954

The "toxicity" of high-pulse diets is thought to be due to a simple deficiency of Ca and P and not to amino-acid imbalance or the absence of an unidentified growth factor, as postulated by earlier authors.—P. C. Jowsey.

5044

DASLER, W. **Partial protection against odoratism (sweet pea lathyrism) by diets high in gelatin or casein.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 485-488. [Dept. Biochem., Chicago Med. Sch., Ill.]

Weanling rats which were given diets containing from 30 to 50 per cent. ground sweet peas and 10 per cent. casein showed gross skeletal malformations within 21 days. High levels of gelatine, 30 per cent., or of casein, 40 per cent., delayed, but did not prevent, the onset of the condition. Casein gave better protection than did gelatine. No explanation can be offered at present for this partially protective action of gelatine and casein. It seems impossible that a deficiency of an essential amino-acid can be the cause of odoratism, since the animals continue to grow and show signs which are quite different from those produced by deficiency of any known amino-acid.

BARNES, J. M. and DENZ, F. A. **The reaction of rats to diets containing octamethyl pyrophosphamide (Schradan) and oo-diethyl-S-ethyl-mercaptoethanol thiophosphate ("Systox").** *Brit. J. Indust. Med.*, 1954, **11**, 11-19. [Toxicol. Res. Unit, Serum Res. Inst., Carshalton Beeches, Surrey.]

Schradan and Systox are systemic insecticides, being absorbed into the plants they are used to spray. The drugs were incorporated into a stock diet to provide up to 50 p.p.m.; for Schradan 148 rats of both sexes were used, for Systox 120 female rats only.

With Schradan, only the male rats having 50 p.p.m. showed any sign of poisoning. They were weak and underweight for the first 18 weeks of the 52 weeks' experiment, but improved later. With Systox, only the rats having 50 p.p.m. were adversely affected; they showed typical signs of poisoning with a cholinergic drug, but recovered before the end of the 16 weeks' experiment. Tests for chronic toxicity of the conventional type thus showed that 50 p.p.m. Schradan and 20 p.p.m. Systox were harmless to female rats, but in a concentration of 3 p.p.m. both drugs produced a 30 per cent. inactivation of blood cholinesterase. Brain cholinesterase was affected also, and in rats having 20 p.p.m. Systox it was inhibited to the extent of 85 per cent. without sign of poisoning being apparent.

The far-reaching implications of the results are discussed.—E. M. Hume.

GENERAL METABOLISM AND FEEDING HABITS OF ANIMALS OTHER THAN MAMMALS AND BIRDS

KUTSKY, P. B., EAKIN, R. M., BERG, W. E. and KAVANAU, J. L. **Protein metabolism of amphibian embryo. 4. Quantitative changes in free and non-protein amino acids.** *J. Exp. Zool.*, 1953, **124**, 263-277. [Dept. Zool., Univ. California, Berkeley.]

For earlier work see Absts. 1046, Vol. 22; 840, Vol. 21 and 5613, Vol. 20.

Quantitative changes in 7 free and 12 total non-protein amino-acids were investigated by microbiological estimation and by paper chromatography in 14 stages of development from the un-

fertilised egg to the completed neurula of *Rana pipiens*. No generalised pattern of behaviour of either free or total non-protein amino-acids was found. With the exception of glutamic acid, correlations with morphological events were not evident. Glutamic acid increased rapidly throughout the entire cleavage period, dropped sharply to mid-gastrulation, increased to late gastrulation, and showed an irregular decrease to the close of neurulation. The results are discussed in relation to biochemical studies of amphibian and other embryos, and to general studies of protein metabolism.—M. B. Richards.

5050

CHEN, P. S. and RICKENBACHER, J. **Concerning the free amino acids in amphibian development.** *Experientia*, 1954, **10**, 182-183. [Zool. Anat. Inst., Univ. Zürich.] German summary.

Free amino-acids were separated by paper chromatography of extracts from different developmental stages of the newts *Triton palmatus* and *T. alpestris*.

Free aspartic acid and glutamic acid were found in extracts from unfertilised eggs, in quantities sufficient to be separated in extracts of only 5 eggs. In the blastula and gastrula 4 more ninhydrin-positive substances appeared, and in young larvae 2 more, one identified as serine. In older larvae threonine, alanine, valine and leucine were found.

In *T. alpestris* at all stages was found a polypeptide complex consisting of aspartic acid, glutamic acid, serine, glycine, alanine, tyrosine and another unidentified acid. More detailed studies are in progress.—D. Duncan.

RICCERI, G. Sull'assenza di enzimi uricolitici nei Cheloni marini (*Thalassochelys caretta*). [Absence of uricolytic enzymes in loggerhead turtles (*Thalassochelys caretta*).] *Arch. Sci. biol., Bologna*, 1954, **38**, 76-82. [Ist. Fisiol. Umana, Univ. Catania.]

Analysis of 3 specimens of the marine loggerhead turtle *Thalassochelys caretta* by 2 different techniques showed that neither in liver nor kidney was there an enzyme oxidising uric acid. This turtle thus resembles the tortoise (*Testudo graeca*) and the higher reptiles, which lack uricolytic enzymes, and differs from the freshwater tortoise (*Emys europaea*), which has in its liver the enzyme uricoxydrase, capable of oxidising uric acid without formation of allantoin.—M. B. Richards.

EGGERT, M. B. O pitanii sorokskoi sel'di. [The nutrition of the Sorokskoi herring.] *Zool. Zh.*, 1953, **32**, 490-494. [Karelo - Finsk. Otdel VNIROKh.]

Examination of the stomachs of Soroksky herrings indicate that their main food is mesoplankton, the larvae of Cirripedia, *Podon*, *Acartia*, *Centropages*, *Temora* and *Pseudocalanus*. There is very little difference between males and females in intensity of feeding and none between the sexes in the composition of their food.—W. Hughes.

5055

SIROVATSKII, I. YA. O biologicheskoi roli i rybokhozyaistvennom znachenii sudaka v vodokhranilishchakh. [The biological role and importance in fish culture of pike-perch in reservoirs.] *Zool. Zh.*, 1953, **32**, 480-483. [Nauch.-Issled. Biol. Inst., Rostov Gosud. Univ.]

From fish breeding experience on the Veselovsky reservoir over a number of years it has been shown that the pike-perch is of importance for the following reasons: it feeds on fish of low marketable value and so frees food reserves for more valuable fish; it suppresses the breeding of perch which as well as preying on other more valuable fish also compete with them for food; it feeds on bream only when great numbers of these breed and it hardly touches carp; it is marketable also.

W. Hughes.

5056

RICCERI, G. Interrelazioni fra le diverse forme dell'azoto nelle uova di *Bombyx mori* durante lo sviluppo embrionale. [Interrelations between the different forms of nitrogen in the eggs of *Bombyx mori* during embryonic development.] *Arch. Sci. biol., Bologna*, 1954, **38**, 89-95. [Ist. Fisiol. Umana, Univ. Catania.]

During development of the egg of the bumblebee, *Bombyx mori*, the amino-N of the mono-acids decreased by 177 mg. and the non-amino-N increased by 60 mg. per 100 g. egg, while the values of melanin N, amido-N and basic N did not change. Taking these results in conjunction with the earlier finding (Abst. 2122, Vol. 23) that the di-amino-acids were unchanged during the development of the egg, it is suggested that the precursors of the purine nucleus in the egg of *Bombyx mori* are to be sought among the mono-amino-acids.

ROCKSTEIN, M. and KAMAL, A. S. **Distribution of digestive enzymes in the alimentary canal of larvae of flies of medical and veterinary importance.** *Physiol. Zool.*, 1954, **27**, 65-70. [Labs. Zoophysiol., State Coll. Washington, Pullman.]

5058

GRAY, H. E. and FRAENKEL, G. **The carbohydrate components of honeydew.** *Physiol. Zool.*, 1954, **27**, 56-65. [Dept. Entomol., Univ. Illinois.]

Honeydew is the liquid excreted by certain insects after ingestion of large amounts of plant sap.

The insect selected was the citrus mealy bug, *Pseudococcus citri*, Risso. Nothing would induce the bugs at any age or stage to feed on any sort of artificial diet, so they were allowed to feed on the sap of Irish potato sprouts. The sap and the honeydew excreted were analysed. In honeydew, chemical tests showed the presence of uric acid, fructose and glucose, but not of dextrin. Studies of the carbohydrate content by paper chromatography with *n*-butanol, ethanol, acetone and water as solvent, and benzidine and trichloroacetic acid spray as developer, showed the presence of fructose, glucose, sucrose, fructomaltose (a recently discovered trisaccharide) and glucose-1-phosphate.

The mealy bugs suck the sap from the sieve-tubes of the phloem, but it was not possible to collect from the sieve-tubes separately, so the total sap of the potato sprouts was analysed. The carbohydrates revealed in the sap by paper chromatography were fructose, glucose, sucrose and glucose-1-phosphate, but not fructomaltose. The last is regarded as a product of digestion, and its presence in honeydew is taken as evidence that the honeydew is not, as has been suggested, the product of a simple process of filtration.

LIPKE, H., FRAENKEL, G. S. and LIENER, I. E. **Growth inhibitors. Effect of soybean inhibitors on growth of *Tribolium confusum*.** *J. Agric. Food Chem.*, 1954, **2**, 410-414. [Dept. Entomol., Univ. Illinois, Urbana.]

Soyin, crystalline trypsin inhibitor, and alkaline, acid or ethanol extracts of soya beans were without effect on the growth of larvae of *Tribolium confusum* or *Tenebrio molitor*. Material precipitated by ammonium sulphate from an extract made at pH 4.6 from raw soya beans was toxic to all larvae when included at 2.5 per cent. of the diet. The extract also depressed the activity of vertebrate trypsin *in vitro*.

Vol. 24, No. 4

Growth of larvae on diets containing raw soya beans was poor, and the relative freedom of stored soya beans from insect attack may be due to a toxin.—D. Duncan.

5060

FRAENKEL, G. and PRINTY, G. E. **The amino-acid requirements of the confused flour beetle, *Tribolium confusum*.** *Duval. Biol. Bull.*, 1954, **106**, 149-157. [Dept. Entomol., Univ. Illinois, Urbana.]

The diets contained casein or amino-acid mixture 15 parts, maize starch 85, salt mixture 2 and vitamin B₁, riboflavin, nicotinic acid, pyridoxine, pantothenic acid, choline, inositol, folic acid and biotin. Each vial contained 10 first-stage larvae on 1 g. dry diet. The efficiency of the diet was assessed by the number and average weight of larvae surviving when those on control diet reached full growth, and also by the time taken to reach pupation.

Tribolium larvae grew as well on the mixture of 19 amino-acids used by Rose *et al.* (Abst. 4591, Vol. 18) as on casein, but growth was slower on the same authors' mixture of 10 amino-acids. The mixture used by Almquist and Grau (Abst. 3386, Vol. 14) was much inferior. Larvae of *Tenebrio molitor* and *Dermestes vulpinus* failed to grow on any of these mixtures.

Starting from the mixture of 10 amino-acids essential for rats, each proved essential also for *Tribolium*. Each of the 9 "non-essential" amino-acids in the mixture of 19 could be omitted without noticeable ill effect, though growth was always faster with the 19 than with the 10. None of the amino-acids was toxic in double the usual amount. D-Forms of methionine, phenylalanine and possibly lysine were fully or partly used, but D-forms of the other amino-acids were inactive.—D. Duncan.

5061

NOLAND, J. L. **Sterol metabolism in insects. 1. Utilization of cholesterol derivatives by the cockroach *Blattella germanica* L.** *Arch. Biochem. Biophys.*, 1954, **48**, 370-379. [Med. Labs., Army Chem. Centre, Md.]

Newly hatched nymphs of the German cockroach (*Blattella germanica*, L.) were fed on synthetic diets containing a series of 41 sterol derivatives. Growth response was then estimated from the average weight of the nymphs at 30 days of age or the average age at which maturation occurred.

Nymphs given the basal diet without sterol survived, but gained little weight. Addition of increasing amounts of cholesterol up to 0.05 per cent. of the diet occasioned an almost linear growth response; further addition of cholesterol caused only a slight increase in growth. With sterol

derivatives a free or esterified hydroxyl group at position 3 was essential for growth, but ring unsaturation at position 5 was not. Cholesteryl chloride had an adverse effect on growth; this effect was reversed when excess cholesterol was given.

The results are discussed in relation to the possible participation of a cholesterol esterase in sterol absorption by insects.—G. A. Garton.

NOLAND, J. L. **Factors influencing the biosynthesis of cholesterol by the cockroach.** *Federation Proc.*, 1954, **13**, 106–107. [Chem. Corps Med. Lab., Army Chem. Centre, Md.]

5063

REDDY, D. B. and MICHELbacher, A. E. **Nature of food and its influence on rice weevil.** *J. Econ. Entomol.*, 1953, **46**, 1098. [Univ. California, Berkeley.]

Rice weevils (*Sitophilus oryzae*, L.) were reared from the egg at 26.6° C. and 70 per cent. relative humidity in ordinary wheat grains or the same wheat boiled for 1 hr. and allowed to dry; the moisture contents of the wheat were 13.6 and 12.2 per cent., respectively.

Weevils took on the average 33 days to emerge from boiled wheat and 30 days from unboiled wheat, but were heavier, average 1.39 mg. compared with 1.20 mg., despite the fact that the moisture content of the unboiled wheat was more favourable for the development of weevils. The percentage increase in weight in 4 months was slightly greater for weevils on unboiled wheat.

It was concluded that boiling may have affected the physical or chemical properties of the wheat or the availability of nutrients.—W. M. Deans.

5064

MISBA, J. N. and RANGANATHAN, V. **Digestion of cellulose by the mound building termite, *Termes (Cyclotermes) obesus* (Rambur).** *Proc. Indian Acad. Sci. [B]*, 1954, **39**, 100–113. [Tech. Development Establishment Labs., Kanpur.]

Cellulase and cellobiase activity were studied in extracts of the gut of worker termites. The enzymes were extracellular, and bacterial cultures

prepared from the gut did not enhance the activity of gut extracts. There was slight cellobiase activity in the foregut and midgut, but most of the cellobiase and all the cellulase were in the hindgut.

King, queen, alate, soldier and nymph termites had no cellulase, but king, queen and alate forms had cellobiase.

Some characteristics of the enzymes are described.—D. Duncan.

GIESE, A. C., BRANDT, C. L., JACOBSON, C., SHEPARD, D. C. and SANDERS, R. T. **The effects of starvation on photoreactivation in *Colpidium colpoda*.** *Physiol. Zool.*, 1954, **27**, 71–78. [Dept. Biol. Sci., Stanford Univ.]

The injurious effect of ultraviolet light on certain organisms is reversed or "photoreactivated" by subsequent illumination with visible light.

The protozoa were starved for 48 hr. Their rate of division was estimated when fed or starved and subjected to a series of doses of ultraviolet light of wavelength 265.4 mμ., with or without subsequent reactivation by measured amounts of blue light of wavelength 435 mμ.

On exposure to ultraviolet light, division was much more retarded in starved colpidia than in fed ones. Much larger doses, up to a certain limit, of blue light were needed to reactivate colpidia that had been starved before exposure to ultraviolet light. The dose of blue light needed increased with the dose of ultraviolet light given. Blue light in excess of a certain amount had a retarding and not a reactivating effect on starved but not on unstarved colpidia. Starved and unstarved colpidia received some protection if they were exposed to daylight before exposure to ultraviolet light. Feeding starved colpidia after exposure to ultraviolet light and before exposure to blue light had little auxiliary beneficial effect.

PRAIS, S. J. **The estimation of equivalent-adult scales from family budgets.** *Econ. J.*, 1953, 63, 791-810. [Dept. Appl. Econ., Univ. Cambridge.]

A quantitative study was made of the effects of household composition on expenditure. Comparisons are made between the effects on consumption resulting from the addition of a person of some particular age-sex group and those resulting from the addition of a standard person, taken as an adult male. Other types are thus measured as fractions of the adult male and so, for any household, the number of equivalent adult males may be expressed in terms of these coefficients. There will be a different set of coefficients, specific to each separate item of consumption, and also a general set, associated with the overall household income per equivalent adult, which will be a weighted average of all the specific sets. Household consumption of one commodity per equivalent adult male may be supposed to be some function of household income per equivalent adult male, and thus total consumption of the commodity will be affected both by the specific and by the general (income) equivalent adult scales.

Vol. 24, No. 4

The theoretical framework developed along these lines is applied to a sample of 2200 family budgets collected in the United Kingdom in 1937-38, and specific scales are calculated for 6 different groups of foodstuffs and for total food. Eight different types of person are distinguished, from infants under one year to adult males. In the calculation the general coefficients were all taken equal to unity, as the simplest first approximation. Once the specific scales were all derived they could be used to give a more accurate general scale, and the calculations were then repeated. Some assumption is necessary concerning the nature of the functional dependence of mean consumption on mean income. Two possibilities are in fact investigated and both are found to give very similar results. The least squares solutions to the equations set up were found by an iterative process using the Cambridge electronic computer.

While the paper is primarily concerned to describe a method of analysis, the results are also given, and show that in the sample investigated females consumed about 15 per cent. less than males, and children under school age about 50 per cent. less.—I. McDonald.

5071

CHAKRAVARTI, N. and BANDYOPADHYAY, K. S. **A note on the consumption of cereals per adult unit in Calcutta.** *Sankhyā, Indian J. Statistics*, 1953, 13, 215-218. [State Statist. Bur., Govt. W. Bengal.]

The data were from those collected in the Family Budget Enquiry 1950-51 made by the West Bengal Government; they referred to the total monthly consumption of cereals by 5 units, adult male, adult female and children 10 to 14, 6 to 10 and 2 to 6 years of age. Total monthly expenditure levels of Rs. 101 to 200 and 201 to 350 only were considered; the numbers of families and persons in the groups were 400 and 1937, 374 and 2360, respectively. At the lower level consumption was 13.85, 12.50, 11.45, 8.03 and 7.10 and at the higher 13.83, 13.32, 10.91, 9.59 and 8.20 seers for the respective age groups (1 seer = 2 lb.). From these data conversion factors were calculated, 1.00, 0.90, 0.83, 0.58 and 0.51 for the lower and 1.00, 0.96, 0.79, 0.69 and 0.59 for the higher expenditure group and they are compared with the Lusk factors and those proposed by Aykroyd (*Abst.* 2277, Vol. 10). It is concluded that consumption of cereals in Calcutta is probably slightly short of requirement.—D. Harvey.

FEEDING OF INFANTS AND CHILDREN

CAMPBELL, W. A. B. and CHEESEMAN, E. A. Some aspects of breast-feeding in Belfast. *Brit. J. Prev. Social Med.*, 1954, 8, 51-58. [Royal Maternity Hosp., Belfast.]

The incidence of breast feeding among mothers confined at the Royal Maternity Hospital was compared with that among mothers confined elsewhere in Belfast. Of 279 live births in the hospital group 242 infants were followed for 6 months; the number of controls followed was 258.

The results showed no appreciable difference between hospital and control groups and combination of the groups gave a picture representative of Belfast. At the end of the first week about

three-quarters, at the end of the first month one-half, and at the end of 2 months one-third of the infants were wholly breast fed.—F. C. Aitken.

JOCHIMS, J. and WILCKHAUS, I. Über die Eignung von "Sterilmilch" zur Ernährung von Säuglingen. [Suitability of "sterile" milk for infant feeding.] *Ztschr. Kinderheilk.*, 1954, 74, 530-546. [Kinderklin., Staät. Krankenhaus Süd, Lübeck.]

Feeding experiments were made with 477 infants of ages from birth to 10 months to test whether sterile milk prepared by the Stork procedure is suitable for infant feeding. The sterile milk diets were compared with similar diets prepared from milk with the same fat content which had been pasteurised and again heated to 90° C. All diets contained $\frac{1}{2}$ or $\frac{2}{3}$ milk with rice gruel (Reisschleim) or Mondamin and 5 per cent. sugar, vitamins being supplied by fruit or vegetables. The average duration of the observation periods was 26.4 days. In the sterile milk group 49.8 per cent. of the infants progressed without disturbance, in the pasteurised milk group 56.4 per cent. The difference between groups did not quite reach statistical significance but it cannot be ignored. Moreover, in all aspects, except resistance to infection, which was the same in both groups, the pasteurised milk group did slightly better than the sterile milk group. Examples of this were in the occurrence of dyspepsias and the proportion of slight cases, in the curative value of the diet in dyspepsia, and in tolerance of overfeeding. The difference between the groups is sufficiently great to indicate that the 2 forms of milk cannot be regarded as equal for infant feeding. It is pointed out, however, that where hygiene is less good than in a children's hospital, the better keeping qualities of the sterile milk may give it a value not indicated in the present experiments.—M. B. Richards.

5080

GÜTZLAFF, W. and JOCHIMS, J. Über Magenverweildauer und Labfähigkeit von Sterilmilch. [Retention in the stomach and curdling of

N.A. and R., October 1954

sterile milk.] *Ztschr. Kinderheilk.*, 1954, **74**, 547-552. [Kinderklin., Städt. Krankenhaus Süd, Lübeck.]

X-ray photographs of 40 infants showed that when a diet was prepared with sterile instead of pasteurised milk, the emptying time of the stomach was shortened by 21.8 min. Studies *in vitro* showed that sterile milk did not curdle with rennet in weak acid and that addition of calcium lactate restored the effectiveness of the rennet. It is assumed that changes in the soluble salts and proteins during the sterilisation process were responsible for both phenomena.—M. B. Richards.

5081

WALTNER, K., TÖRÖK, J. and KOMÁROMI, O. Die Bedeutung des Invertzuckers in der Säuglingsernährung. [**Importance of invert sugar in infant feeding.**] *Acta med. hung.*, 1954, **5**, 415-417. [Kinderklin. Med., Univ. Szeged.]

From experience with both sick and healthy infants it is recommended that invert sugar be used exclusively in the preparation of both diluted milks and curative diets, instead of ordinary sugar and foods containing dextrin and maltose. The tolerance of infants for invert sugar is considerably better than for ordinary sugar, and permits the intake of greater amounts without disturbance, a matter of importance in illness. Preparation and use of the invert sugar is extremely simple; boiling of the sucrose for 5 min. with the amount of citric acid generally used for acidifying infants' food converts it completely to dextrose and fructose, and the required amount of starch or cereal can then be added to this solution. Boiling 1.5 g. citric acid in 50 ml. water with 80 g. sugar for 5 min. and diluting to 100 ml. gives a syrup containing approximately 4 g. invert sugar in 5 ml. This syrup, besides being used for the ordinary sweetening of infants' diets, has been given regularly to infants with hepatitis.—M. B. Richards.

5082

BARTA, L. and NÉMETH, E. **Fat tolerance tests in infants.** *Acta med. hung.*, 1954, **5**, 231-240. [1. Dept. Paediat., Med. Sch., Univ. Budapest.] Russian summary.

A group of 21 infants, of which all except 4 were over 6 months of age, were given after an 8-hr. fast 2 g. butter per kg. bodyweight in tea containing 5 per cent. sugar. A control group were treated similarly except that butter was not given. The fatty acid content of the blood was estimated fasting and 4, 5 and 6 hr. after butter. The daily fluctuations of blood fatty acids were studied in a third group of 20 infants on normal diet. In a fourth the effect of a ketogenic diet was studied

in 15 infants. They received their evening meal and at 2 a.m. were given a milk preparation with saccharin. At 8 a.m. they were given 2 g. butter per kg. bodyweight in tea and in the course of the morning they were given 50 to 100 g. unsweetened tea. Total ketones in the blood were estimated fasting, then at midday and 1 p.m.

The infants were graded according to developmental quotient, *i.e.*, ratio of actual weight to normal weight for age; quotients ranged from 0.4 to 1.2. A significant rise in blood fatty acid in response to ingestion of butter occurred in atrophic infants as well as in infants of higher developmental quotients, but atrophic infants on a ketogenic diet did not have the high levels of ketone bodies which were found in the blood of infants of better development when they were given a ketogenic diet.

There was no hepatic dysfunction in the atrophic infants, but pituitary hypofunction is believed to have existed.—F. C. Aitken.

SUR, G., REDDY, S. K., DORAISWAMY, T. R., SANKARAN, A. N., BHAGAVAN, R. K., SWAMINATHAN, M. and SUBRAHMANYAN, V. **Partial replacement of cereals by Mysore flour.** *Bull. Central Food Technol. Res. Inst. Mysore*, 1954, **3**, 85-87.

Forty-eight girls, aged 5 to 11 years, in an institution in Mysore were divided into 2 paired groups, one receiving the ordinary institution diet (poor vegetarian) and the other the same diet but with 2.25 oz. wheat and 2.25 oz. jowar replaced by 4.5 oz. of a mixture of 75 per cent. tapioca flour and 25 per cent. groundnut cake flour (Mysore flour). The experiment lasted for 6 months and height, weight, red blood cells, Hb and nutritional score were estimated before and after the experiment.

No difference was found between the groups except that Hb was significantly higher in the experimental group. It is concluded that Mysore flour can be used in times of scarcity to replace 50 per cent. of the cereals in the diet of children. See also Abst. 3552, Vol. 24.—J. S. Thomson.

5087

REDDY, S. K., SUR, G., DORAISWAMY, T. R., SANKARAN, A. N., SWAMINATHAN, M. and SUBRAHMANYAN, V. **Effect of supplementary composite protein food on the growth and nutritional status of school children.** *Bull. Central Food Technol. Res. Inst. Mysore*, 1954, **3**, 87-88.

The composition per oz. of a food supplement is 22.4 g. protein, 0.166 g. Ca, 0.304 g. P, 2.9 mg. each of vitamin B₁, riboflavin, Ca pantothenate and pyridoxine, 0.9 mg. folic acid and 11.4 mg. nicotinic acid (Indian Patent No. 47580, 1953). Two paired groups, each of 11 girls between 7 and 11 years of age on a boarding school diet, were selected. One was given 1 oz. of the food daily per head, the other a pudding made from 25 g. maize starch, each addition being sweetened with 1 oz. sugar. The experiment lasted for 10 weeks.

Calculated values for the school diet showed inadequacy of energy, protein, Ca and riboflavin. Statistical analyses indicated that the data for height, weight and nutritional deficiency score as defined by the Nutritional Advisory Committee of the Indian Council for Medical Research (Rep. Sci. Advisory Board, 1944) differed significantly in favour of the protein food group; group differences for Hb and red blood cell counts were not statistically significant.—D. Harvey.

5088

REDDY, S. K., SUR, G., DORAISWAMY, T. R., SANKARAN, A. N., SWAMINATHAN, M. and SUBRAHMANYAN, V. **Effect of supplementary composite protein food on the growth and nutritional status of school children.** *Indian J. Physiol. Allied Sci.*, 1954, **8**, 26-33. [Central Food Technol. Res. Inst., Mysore.]

The composite protein food (see previous Abst.) was again tested over 10 weeks on a group of 10 girls between 7 and 11 years of age in an institution, who received 1 oz. daily. On the average their height and weight gains were significantly greater than those of a matched control group given an isocaloric supplement of maize starch and sugar, and their Hb value and nutritional status also improved.—W. M. Deans.

5089

REDDY, S. K., SUR, G., DORAISWAMY, T. R., SANKARAN, A. N., SWAMINATHAN, M. and SUBRAHMANYAN, V. **Institution feeding experiment with a new type of balanced food.** *Bull. Central Food Technol. Res. Inst. Mysore*, 1954, **3**, 136.

Twenty schoolboys aged 10 to 15 years were divided into 2 groups; one received the institution diet, the other the same diet with half of the cereals replaced by the composite food. The experiment lasted for 2 months. Gains in height, weight and Hb during the period were greater in the experimental than in the control group, that in weight being statistically significant. Hip width, red blood cell count and nutritional deficiency score did not show corresponding differences in favour of the experimental group.—D. Harvey.

DIETARY SURVEYS AND INDIVIDUAL STUDIES

5090

WILCOX, E. B. and GALLOWAY, L. S. **Children with and without rheumatic fever. 1. Nutrient intake, physique, and growth. 2. Food habits.** *J. Amer. Dietetic Assoc.*, 1954, **30**, 345-350; 453-457. [Dept. Foods Nutrit., Utah State Agric. Coll., Logan.]

1. For 131 children with a history of rheumatic fever and 131 controls nutrient intakes were computed from 1-week records of food consumption. The girls in the control group were consuming significantly more energy, protein, fat, Fe, vitamin B₁ and nicotinic acid than the girls in the rheumatic fever group. In the rheumatic fever group slightly more children were underweight and of borderline or poor physique than in the control group.

2. Results are presented in terms of servings of 15 food groups. Average daily intakes of the foods were similar for the 2 groups of children. Milk

N.A. and R., October 1954

supplied a higher proportion of total energy, calcium, vitamin B₁ and riboflavin than any other food group.—F. C. Aitken.

5091

NYGREEN, M. S. **Foods eaten by college students. Acceptability, adequacy, and cost.** *J. Amer. Dietetic Assoc.*, 1954, **30**, 359-362. [Lincoln, Nebr.]

Standard portions of each food served in the women's residence halls of a university were weighed for a week and protein, vitamin B₁, riboflavin and ascorbic acid contents were computed. Students eating all of 3 meals daily could obtain the National Research Council's recommended allowances of these nutrients, but many students missed meals or rejected nutritious foods. The average daily cost of food served was 83 cents per head.—F. C. Aitken.

5092

WIDDOWSON, E. M., EDHOLM, O. G. and McCANCE, R. A. **The food intake and energy expenditure of cadets in training.** *Brit. J. Nutrition*, 1954, **8**, 147-155. [Med. Res. Coun. Dept. Exp. Med., Univ. Cambridge.]

The study was on the food intake and energy expenditure for a week of 77 cadets aged 18½ to 20 years in a training establishment of the armed forces. Two groups of observers were present. The cadets themselves recorded their daily intake and activities. The total intake of the 77 was estimated by weighing all the food provided for each meal, the unserved portions and the plate waste and by weighing and measuring the foods and drinks served in the canteen. Food obtained from other sources could not be checked. Recorded activities were compared with the official timetable and are considered to give a "reasonably accurate" picture. "Several" measurements of oxygen consumption were made during fitness training and drill. Energy expenditure on other activities was estimated from the collected figures of Orr and Leitch (*Nutrit. Abst. Rev.*, **7**, 509) and those of Passmore *et al.* (*Abst.* 558, Vol. 23).

The average daily intake of all the cadets was 3705 Cal., 2527 or 68 per cent. from food eaten in the dining hall, 20 per cent. from the canteen and the rest from food obtained outside. The food provided for the cadets could supply 3714 Cal., but only two-thirds was eaten. The greatest wastage of calories was in bread. The average daily energy expenditure was 3420 Cal., the difference between highest and lowest amounting to 775 Cal.

The reasons for the dislike of the official feeding arrangements are discussed. It was clear the failure of the cadets to gain weight was not due to

an insufficient supply of food. The bought food contained more fat and alcohol and somewhat less protein, carbohydrate, Ca and Fe than that provided.—D. Duncan.

5093

MIRONE, L. **Hemoglobin level and dietary intake of adults.** *J. Clin. Nutrit.*, 1954, **2**, 38-42. [Dept. Nutrit., Sch. Home Econ., Univ. Georgia, Athens.] Spanish summary.

Hb values, range and mean, were for 139 men 13.04 to 18.23 (16.13 ± 0.09) and for 396 women 10.39 to 16.83 (13.99 ± 0.05) g. per 100 ml. Heights and weights were measured and the averages are tabulated with percentages over and underweight. No relation was found between the distribution of underweight and Hb values. Subjects were asked to record food intake and from the records nutrient intakes were computed. The mean intakes for men and for women agreed well with National Research Council recommended allowances, except for Ca, where the average intake of the women fell short of the recommended intake.—F. C. Aitken.

5094

KARVONEN, M. J. and TURPEINEN, O. (with ARPPE, M. and LUUKKA, A.) **Consumption and selection of food in competitive lumber work.** *J. Appl. Physiol.*, 1954, **6**, 603-612. [Inst. Occupational Health, Vet. Coll., Helsinki.]

A study was made of the consumption and selection of food by 40 men during the Finnish National Woodcutting Competition of 1951.

Mean values were for energy intake 5460 Cal. daily and for loss of weight by those completing the competition 1.2 kg. The correlation of work performance with food consumption in the individual was not significant and with weight loss only approached significance. The high work output of the competitors was due primarily to economical working methods, not to a higher energy expenditure than that of the average lumberjack. Similarly, within the group of competitors the best workers achieved their results chiefly by greater skill and to a less extent by using more energy. Empirically, the lumberjacks had acquired food habits, such as the use of sugared drinks, which are in accordance with recommendations based on recent physiological research (see also *Abst.* 1008, Vol. 24).

M. B. Richards.

5095

BRANSBY, E. R. **The nutrition of male industrial workers with particular reference to intake and expenditure of calories.** *Brit. J. Nutrition*,

1954, 8, 100-111. [Minist. Health, 23 Savile Row, London, W.1.]

To study the relation of heaviness of work to intake of energy, 174 men were medically examined and, in most, measurements were made of their height, weight and blood pressure and of the Hb and pseudocholinesterase content of blood. Information was obtained also on the grade of their work, classified as light, light to medium, medium to medium heavy, or heavy, and on the time they spent on out-of-work activities. Allowances made for other-than-work exertions were 1.1 Cal. per min. for B.M.R., reduced by 10 per cent. for the period of sleeping; a 6 per cent. addition to basal amounts for specific dynamic action; additions for other activities, based on published and unpublished work by Passmore *et al.* (Abst. 558, Vol. 23). The sum of these expenditures was subtracted from the total intake of energy calculated from a dietary survey made by the weighing method for a week and the difference was used to calculate the energy expenditure per min. according to heaviness of work.

Average weekly consumption for 152 men in the diet survey is tabulated for 21 items of food; largest in amount were bread 77, milk and cream 76, potatoes and chips 62, fruit puddings, pies and milk sauces 35 and meat 31 oz. weekly. Calculated daily nutrient intakes were energy 3549 Cal., protein, vegetable 54 and animal 55, fat 138, carbohydrate 435 and Ca 1.3 g., Fe 21, vitamin B₁ 1.7, nicotinic acid 14, riboflavin 1.8 and vitamin C 42 mg. and vitamin A 4171 I.U.

For 137 men for whom complete data were available and whose nutritional status was satisfactory, average energy intakes for the 4 grades of work were light 3269, light to medium 3446, medium to medium heavy 3476 and heavy 3903 Cal. daily. In the same order average energy expenditures were: on basal metabolism 1550, 1532, 1533, and 1534; on specific dynamic action 93, 92, 92 and 92; on out-of-factory activities 788, 759, 838 and 692 and on work 838, 1063, 1013 and 1585 Cal. The average cost of the grades of work was 2.2, 2.7, 2.6 and 3.8 Cal. per min.

Relative expenditure of time was: work 27.9, sleeping 35.4 and other activities 36.7 per cent. Of the total expenditure of energy on out-of-work activities cycling, sitting, dressing, domestic work and walking accounted for 20.6, 19.8, 17.4, 16.7 and 13.1 per cent., respectively; the remaining 12.4 per cent. was used in gardening 5.0, games 4.0, standing 2.1 and lying down, fetching and carrying 1.3.

An earlier finding (Ministry of Health, "On the State of the Public Health", H.M.S.O., 1950) of no difference existing between the intakes of energy by groups of men with different degrees of activity was not confirmed.—D. Harvey.

5096

KEYS, A. and KEYS, M. H. **Serum cholesterol and the diet in clinically healthy men at Slough near London.** *Brit. J. Nutrition*, 1954, 8, 138-147. [Lab. Physiol. Hyg., Sch. Pub. Health, Univ. Minnesota, Minneapolis.]

Serum cholesterol values for 48 healthy men, aged from 40 to 55 years, workers in small factories at Slough, who were known to be consuming a diet supplying on the average 3427 Cal. daily (range 2095 to 4942), of which 35.4 per cent. (range 28 to 43) came from fat (for details see previous Abst.), were compared with those for men of similar age in Minnesota (Abst. 5242, Vol. 20) and Naples (see next Abst.), who got about 40 and 20 per cent., respectively, of their energy from fat.

The Slough men were thinner than the Americans or the Italians, but are believed to have been representative of Englishmen in both bodyweight and diet. Their serum cholesterol values, mean 250 mg. per ml., S.E. 5.8, were similar to those of the Americans and significantly exceeded those of the Italians (mean 231, S.E. 7.5). In the Slough data there was a correlation between serum cholesterol and age of the type already demonstrated for Minnesota data but not with relative bodyweight, and when the effects of age and relative bodyweight were eliminated, none with the percentage of energy supplied by fat.

The literature on serum cholesterol in man is discussed. A table shows average daily intakes of cholesterol-containing foods and of cholesterol in the United Kingdom and the United States, estimated both from dietary surveys and from national food consumption data, from which it is clear that the daily cholesterol intake in the United States is possibly twice that of working-class people in the United Kingdom. But serum cholesterol is not related to cholesterol intake and it is only when the percentage of calories from fat is high (of the order of 30 per cent. or more) that serum cholesterol rises in middle age.

W. M. Deans.

5097

KEYS, A., FIDANZA, F., SCARDI, V., BERGAMI, G., KEYS, M. H. and DI LORENZO, F. **Studies on serum cholesterol and other characteristics of clinically healthy men in Naples.** *Arch. Int. Med.*, 1954, 93, 328-336. [Lab. Physiol. Hyg., Sch. Pub. Health, Univ. Minnesota.]

In a group of 83 men serum cholesterol rose by about 3 mg. per 100 ml. per year from age 20 to the early thirties, a rise which corresponded to that found in men of the same age in Minnesota. Thereafter, unlike the Americans, the Italians showed no further age trend, so that by age 50 there was a mean difference of about 30 mg. per 100 ml. between the Italians and the Americans.

N.A. and R., October 1954

In the Italians, as in the Americans, no relation was found between serum cholesterol and relative obesity. Electrocardiographic age trends which were clear in the Americans were small or absent in the Naples group.

The men studied in Naples were consuming diets which conformed to the Italian national diet pattern of 20 per cent. of energy from fat, and they were judged to be at least as obese as their American counterparts who consumed diets of which 40 per cent. of the energy was from fat.

The results are discussed, and it is pointed out that the incidence of coronary and myocardial disease among middle-aged men is much greater in the United States than in Italy.—F. C. Aitken.

KEYS, A., VIVANCO, F., RODRIGUEZ MIÑON, J. L., KEYS, M. H. and CASTRO MENDOZA, H. **Studies on the diet, body fatness and serum cholesterol in Madrid, Spain.** *Metabolism*, 1954, **3**, 195–212. [Lab. Physiol. Hyg., Sch. Pub. Health, Univ. Minnesota, Minneapolis.]

Height, weight and skinfold thicknesses were measured and serum cholesterol was estimated in 60 men and 61 women living in Vallecas, a poor sector of Madrid, and in 61 professional men.

A one-week diet study of the Vallecas families showed a low energy intake, with total fats accounting for 27 per cent. of the total. The diets of the professional men appeared to be high in energy and fat and conformed to average United States intakes.

At all ages the Vallecas men were shorter and thinner than the professional men. The latter and the older Vallecas women conformed closely to United States standards for relative bodyweight; the younger women were usually thin.

Serum cholesterol values in the professional men and in the younger Vallecas men were similar to values obtained in a study of Americans in Minnesota, but in the Vallecas men values tended to decline from the middle thirties instead of rising, so that at ages 45 to 55 years they were much lower than in the professional men and Minnesotan men of the same age. In the women values tended to rise with age to about 40 years with little further change. The class difference in serum cholesterol was not ascribable to relative obesity, but within the Vallecas groups serum cholesterol was positively correlated with relative bodyweight. Re-analysis of data obtained 10 years earlier in Madrid gave good agreement with the present data. Comparison of the serum cholesterol values with data obtained elsewhere showed that at age 45 years and older values for the Vallecas men were similar to those for Neapolitans with 20 per cent. of energy from fat, whereas those for the professional men were of

the same order as for Londoners with 35.4 per cent. of energy from fat and for the Minnesotans with about 40 per cent. of energy from fat.

The data are discussed with reference to the indication from vital statistics that degenerative heart disease is much less common among Spanish men than among Americans of the same age.

HARDINGE, M. G. and STARE, F. J. **Nutritional studies of vegetarians. 1. Nutritional, physical, and laboratory studies. 2. Dietary and serum levels of cholesterol.** *J. Clin. Nutr.*, 1954, **2**, 73–82; 83–88. [Dept. Nutr., Harvard Sch. Pub. Health, Boston, Mass.] Spanish summary.

1. Of 200 subjects studied, 86 were lacto-ovo-vegetarians, 26 were pure vegetarians and 88 were non-vegetarians. The subjects were adults, adolescents and pregnant women. There was only 1 adolescent and no pregnant woman among the pure vegetarians. Diets were studied by the diet history method, the course of pregnancy was recorded, physical examinations were made and laboratory tests of blood included estimations of blood pressure, packed cell volume, red cell counts, total and differential white cell counts, serum protein, albumin and globulin.

Group average intakes of nutrients approximated to U.S. National Research Council recommended allowances. Physical examinations, laboratory tests and studies of the course of pregnancy revealed no significant difference between vegetarian and non-vegetarian except that pure vegetarians were lighter in weight than non-vegetarians and lacto-ovo-vegetarians although their energy intakes were almost the same.

2. In the 3 groups cholesterol intakes were computed and serum cholesterol was estimated. Intake was higher among non-vegetarians than among lacto-ovo-vegetarians; the diets of pure vegetarians were cholesterol-free. Serum cholesterol values within a group were not related to bodyweight but tended to increase with advancing age. The adult non-vegetarians had higher serum cholesterol values than adult lacto-ovo-vegetarians; both groups had higher values than adult pure vegetarians.

No case of hypertension occurred among pure vegetarians; its frequency of occurrence was about the same in the non-vegetarian and lacto-ovo-vegetarian groups.—F. C. Aitken.

CLARK, F. and FINCHER, L. J. **Nutritive content of homemakers' meals. Four cities, winter 1948.** *U.S. Dept. Agric., Agric. Information Bull.* No. 112, March 1954, pp. iv + 67.

Over 1000 housewives supplied estimates of quantities of foods eaten by them in the 24 hr. preceding the interview. Results are presented in terms of foods and nutrients. The average diet was low in calcium and riboflavin and supplied only 1780 Cal. The effects of age and socioeconomic circumstances on the nutritive value of the diet, the contribution of each meal to the day's food and the nutritive content of food consumed at home and away from home, are analysed.

BAUM, E. L. and CORBRIDGE, I. L. **Household income, food expenditures and desires in Seattle, Washington.** *J. Farm Econ.*, 1954, **36**, 135-139. [State Coll. Washington.]

A study of food expenditure over 2 weeks of 646 randomly selected households in Seattle in September 1950 showed the usual tendency for the percentage of household income spent on food to decline with increasing income. Sixty per cent. of those with an income of \$2000 or under would have liked to spend more on food, but only 24 per cent. of those with over \$5000. The strongest desire was for more and/or better meat and poultry; next, but well behind, came fruit and vegetables, and milk, almost level.

The economic implications are discussed and it is concluded that a food subsidy to low-income groups to insure minimum standards of nutrition in times of depression would tend to increase and stabilise food consumption.—W. M. Deans.

5102

JORDAN, M., KEPES, M., HAYES, R. B. and HAMMOND, W. **Dietary habits of persons living alone.** *Geriatrics*, 1954, **9**, 230-232. [Westchester County Dept. Health, White Plains, N.Y.]

Diet histories were obtained from 24 men and 76 women, aged 65 or older, living alone. Diets were compared with a standard diet in terms of servings of 7 food groups. The outstanding shortcomings of the diets were underconsumption of yellow and leafy green vegetables, dairy products, and citrus fruits, tomatoes or salad greens.

5103

MCGANITY, W. J., CANNON, R. O., BRIDGFORTH, E. B., MARTIN, M. P., DENSEN, P. M., NEWBILL, J. A., MCCLELLAN, G. S., CHRISTIE, A., PETERSON, J. C. and DARBY, W. J. **The Vanderbilt cooperative study of maternal and infant nutrition. 5. Description and outcome of obstetric sample. 6. Relationship of obstetric performance to nutrition.** *Amer. J. Obstet. Gynecol.*, 1954, **67**, 491-500; 501-527. [Div.

Nutrit., Dept. Biochem., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

For Parts 1 to 4 see Abst. 3558, Vol. 24.

5. The obstetrical histories of the patients are described and comparable data from the literature are summarised.

6. Between 10 and 15 per cent. of the mothers developed one or more clinical abnormality of pregnancy, labour and puerperium, and 25 of these abnormalities were differentiated for study, the nutritional status of the patients concerned being compared with the picture determined for the complete group. It is assumed that "when gestation was uneventful minor aberrations in the over-all nutritional status of the mother were of no real importance". For the whole group of 2046 patients, average nutrient intakes fell somewhat below U.S. National Research Council recommendations, and a general decrease was found during the third trimester compared with earlier stages of pregnancy. No case of frank deficiency disease was found, and "in the realm of so-called 'subclinical signs' of dietary deficiency, extreme inconsistencies between examiners emphasised the nebulous nature of many of the proposed stigmas".

A series of tables compares the dietary and laboratory findings for the abnormal subgroups with those for the whole group. In general, the findings were either negative or "the occurrence of statistically significant differences is a reflection of the large groups involved. The actual arithmetical differences are small and the averages compared are made up of overlapping individual values." The more interesting findings included, among pre-eclamptic and eclamptic patients low nutrient intakes generally, significantly low only for nicotinic acid and total energy. On the other hand, these patients were more obese than average, and their slightly reduced intakes seem to have resulted from medical advice to reduce consumption. The mothers of premature infants were more liable than average to have been classified as clinically undernourished, but the only dietary finding to match was a below-average intake of ascorbic acid. Mothers who took less than 1500 Cal. and 50 g. protein daily during the third trimester had a high incidence of pregnancy disease in general. In summary, from this study in the United States "there is no clear indictment of nutritional lack as an important aetiological agent in the numerous conditions studied".

MACY, I. G., MOYER, E. Z., KELLY, H. J., MACK, H. C., DI LORETO, P. C. and PRATT, J. P. **Physiological adaptation and nutritional status during and after pregnancy.** *J. Nutrition*, 1954, **52**, Suppl. 1, pp. 92. [Res. Lab., Child. Fund Michigan, Detroit.]

Three groups of pregnant women were investigated: (1) 109 white and 844 negro low-income hospital patients; (2) 33 white and 131 negro patients of moderate economic status who attended a hospital private clinic; and (3) 230 white private patients described as "middle-class with a few wealthy individuals". From these, 160 white and 267 negro patients were chosen to form "selected groups", representing those in whom gestation and delivery was uncomplicated and who delivered healthy term infants weighing at least 2500 g. Numerous biochemical estimations were made on blood samples. Women in groups 2 and 3 recorded qualitative 7-day food intakes early in pregnancy and at least once in each trimester, and 24-hr. "recall" records supplemented by brief dietary histories were obtained for those in group 1. The quality of diets was evaluated relative to the U.S. National Research Council recommended allowances for pregnant women by a scoring system based on average weekly helpings of 7 main food groups. The groups of patients in each race were compared in terms of median age, stature, pre-gravid weight, weight change during pregnancy and proportions in each category of diet quality and of quality of prenatal care. It was concluded that differences were unimportant except those for race, dietary quality, and quality of prenatal care. Of the diets of white patients twice as many of group 1 as of those of higher socio-economic status selected from groups 2 and 3 were classified as incompatible with full health. All the negroes, including those in the selected group, had sub-standard dietaries, comparable to those of the low-income whites in group 1. Antenatal care was also inferior for negroes, except in group 1. Birthweights in each racial group tended to rise with economic status but were not related to diet ratings or to estimated protein intakes. They were higher among women considered to have had "good" than "poor" prenatal care.

The bulk of the report is devoted to presentation of the results for blood chemistry. Median and 10th and 90th percentile levels are given, for selected group white and negro patients separately in each month of pregnancy, for the following: Hb, and serum protein, alkaline phosphatase, vitamin A, carotenoids and vitamin C. Values for infants and for non-pregnant women are compared. Median levels are also given, for each group investigated, by race and by trimester of pregnancy. Generally speaking, differences between the economic groups, where present, were inconsistent and were overshadowed by differences between races and by changes in level during the course of pregnancy. Negro levels were lower than white for Hb, and for serum vitamin A, carotenoids and vitamin C; the

reverse was true for serum protein; there was little or no racial difference in serum alkaline phosphatase. There was some evidence of a relation between serum vitamin A and vitamin C and diet ratings. Serum vitamin C levels in the selected group of whites tended to be high compared with those for white patients as a whole.

TRÉMOLIÈRES, J., *et al.* Étude de la consommation à Marseille (mars-avril-mai 1953). [Study of consumption in Marseilles (March-April-May 1953).] *Bull. Inst. nat. Hyg., Paris*, 1954, 9, 298-340.

This study of household habits was made on 1014 randomly selected families (3331 persons) in Marseilles in the spring of 1953, but the questionnaire was not the same as that used in previous studies (Abst. 884, Vol. 21); the emphasis was on shopping habits. Nevertheless, from particulars of the foods most recently purchased certain conclusions about diet are drawn. Mean daily energy and nutrient intakes and consumption of food items are tabulated for the whole sample and for families classified in 4 economic categories. The all-over mean values were: Cal., with beverages 3048, without 2883; carbohydrate 343, animal protein 46, vegetable protein 42, fat 127 g.; Ca 1116, Fe 20 mg.; vitamin A 645, vitamin B₁ 1668, riboflavin 1774 μ g.; vitamin C 176 mg. By the criteria previously used the diets were considered adequate except in the poorest group. Fat consumption was large. Consumption of all foods except fish and dried vegetables was greater than in the 1952 inquiries, which, however, were based on a week's purchases. About a third of the housewives considered fish more economical than meat, and about the same proportion, more in the most prosperous group, considered that milk and cheese could to some extent take the place of meat. The two most prosperous groups were satisfied with their diets; in the others, meat was the item of which most wanted more. Most food is bought locally, especially in the suburbs. The weekly rhythm of shopping is shown in great detail in tables and diagrams.—W. M. Deans.

5106

BOUCHE, A. Enquête sur les budgets familiaux par carnets de comptes annuels à Marseille (octobre 1951-septembre 1952). [Study of family budgets in Marseilles by questionnaire on annual expenditure (October 1951-September 1952).] *Bull. Inst. nat. Hyg., Paris*, 1954, 9, 341-392. [Sect. Nutrit., Inst. Nat. Hyg., Marseilles.]

Sixty-six families, with 233 persons and classified in 3 occupational groups, voluntarily kept accounts

for a whole year, and these are analysed exhaustively in tables and graphs according to group and size of family. Nearly half the paper is devoted to details of expenditure on food. This formed from 43 to 53 per cent. of total expenditure and showed peaks in December and July or August. In all 3 groups meat and fish accounted for 27 per cent. of food expenditure and were as important as clothing in the total budget; next came fruit and vegetables 16 to 18, bread and cereals 13 to 15, and milk and cheese, about 10 per cent. Of the meat and fish items, most was spent on beef. The percentage spent on milk and cheese did not vary much with occupational group or size of family. Expenditure on fat, 7 to 8 per cent., was about equally divided between oil and butter and little lard or margarine was used. For the whole group the foods on which most was spent were bread, beef, wine, fresh fruit, fresh vegetables, milk, cheese, bacon and ham, oil, fresh fish, in that order.—W. M. Deans.

SOGANDARES, L., DE GALINDO, A. P. and MEJÍA, H. P. Estudios dietéticos de grupos urbanos y rurales de la República de El Salvador. [Diet studies on urban and rural populations in El Salvador.] *Bol. Ofic. sanit. panamer.*, 1953, Suppl. 1, 27–37. [Inst. Nutrición de Centro América y Panamá, Guatemala.]

In the rural area the wage earners were employed mostly as day labourers or overseers on coffee estates or as owner-occupiers of small holdings. A small number were employed otherwise as labourers or in commerce. About 34 per cent. of wage earners were women. Average family size was 6.6 and the total population surveyed numbered 319. About half the wage earners in the urban group were women. Average family size was 5.9 and the total population surveyed numbered 113. Food intake was measured daily for 7 days.

The rural population consumed a large amount of maize, 2340 g. per person per week, more than twice as much as the urban group, but

its consumption of meat and dairy products was low. In both populations energy intake was below the recommended level, and in the rural group intake of animal protein did not reach the minimum recommended level. Intakes of vitamins, excluding ascorbic acid which was not measured, were generally low.—P. C. Jowsey.

5110

MOEN, M. L. Consumo de alimentos de trece familias de los empleados de una fábrica de textiles en Quezaltenango, Guatemala, C.A. [Food consumption of the families of thirteen textile workers in Quezaltenango, Guatemala.] *Bol. Ofic. sanit. panamer.*, 1953, Suppl. 1, 37–49. [Inst. Nutrición de Centro América y Panamá, Guatemala.]

Of the 13 families studied, 9 with 56 persons were native Guatemalans and 4 with 23 persons were of Spanish descent. Average family size was 6. Food intake was recorded in detail for 7 consecutive days. Results are presented for Guatemalan and Spanish families separately and together.

For all 13 families, average nutrient intake per person was satisfactory, except for Ca, which averaged 0.9 g. daily, 86 per cent. of the amount recommended, and vitamin A, riboflavin and ascorbic acid, which averaged 1552 I.U., 0.8 mg. and 27 mg. daily, 35, 51 and 40 per cent., respectively, of the amounts recommended.

It is suggested that the people should be educated in the essentials of nutrition and that salt should be iodised to prevent endemic goitre.

P. C. Jowsey.

5111

INDIAN STATISTICAL INSTITUTE. The national sample survey. General report No. 1. First round: October 1950–March 1951. 2. Tables with notes on the second round April–June 1951. *Sankhyā, Indian J. Statistics*, 1953–54, 13, 47–214; 267–324.

1. In this report considerable space is devoted to general descriptions of the situation leading to this economic and social survey of India and of the methods adopted. Some of the difficulties met in planning the survey are given in the main body of the report and also, in greater detail, in the appendixes. In the first appendix the uses of the different types of form are described with the procedures adopted in sampling for different purposes. Samples of the forms used are also given in the final appendix.

The country has been divided into 6 zones, described in the first 5 tables, and the results of the survey are presented in 2 ways. First, for each zone separately, the expenditure per household over the year July 1949 to June 1950 is broken down into 42 different items of expenditure.

N.A. and R., October 1954

[The difference in dates is explained by 2 sets of schedules having been used.] Secondly, for each of these items separately, the expenditure per household and per person is shown for the 6 zones.

A portion of the report is devoted to comments on these results, and to the development and future programme of the survey.—A. W. Boyne.

2. Selected results are given which were obtained in the period April to June 1951 in the second round of the National Sample Survey of India. This is now established on a continuing basis and conducts surveys in a number of successive rounds each year. The report is less general in its scope than that on the first round, and presents data on five main topics; a comparison of consumption patterns in the first and second rounds; the distribution of households by size of consumer expenditure; the analysis of consumption into 2 parts, that of home production and that involving monetary outlay; estimates of rural capital formation; the distribution of households by the size of lands operated or managed by them. Notes are given for each set of data to explain the concepts and definitions that were used in compiling them.—I. McDonald.

5112

WILSON, D. C. **The nutrition of schoolgirls in Northern Nigeria.** *Brit. J. Nutrition*, 1954, 8, 83-89. [Lab. Human Nutrit., Univ. Oxford.]

Girls aged 10 to 18 years in government boarding schools, in Native Authority senior and junior primary day schools and in schools of voluntary agents were examined. Records of the nutritional status of 284 subjects were made in the form described by Sinclair, "Malnutrition and Starvation in Western Netherlands", General State Printing Office, The Hague, 1948. Young Berum mothers, 24 in number, in the maternity wards of a "bush" hospital were also examined.

The dietary patterns are tabulated for the subjects arranged in 8 racial groups and in terms of 41 foods in 13 groups according to amounts used; negligible, seasonal, i.e., negligible in dry seasons, small or considerable. The mineral salts in the diet are also described. Clinical data are summarised for the dry season.

It is concluded that the nutritional status of the girls reflects the level of the agricultural economy of the community and that the intake of energy by the poorer members is low. A seasonal shortage of vitamin C may also occur.

In some mixed schools the status of the boys [number not stated] was also studied and was found to be below that of the girls. The girls ate with the women who prepared the food and so may have had more liberal amounts than did the boys.

GENERAL STUDIES: DIET PLANNING: EDUCATION

5113

COOK, P. H. and WYNDHAM, A. J. **Patterns of eating behaviour. A study of industrial workers.** *Human Relations*, 1953, 6, 141-160. [Austral. Dept. Labour Nat. Serv.]

It was desired to ascertain whether a community such as the workers in a factory has variations in the pattern of eating in accordance with the social structure and culture of groups within the community. The factory selected was owned by the Australian Government, and made and stored armaments. The staff included 39 on administration, 106 on production and 125 in the store; 95 per cent. were males, of whom 75 per cent. were married. [The date is not specifically stated but seems to have been 1950-51.] By observation, questionnaire and interviews the study investigated what was eaten, when, where and how. There was a cafeteria within the factory and no other place served meals within 10 min. walking distance.

Morning tea was taken without leaving the place of work. Luncheon was taken at midday, 40 min. for administrative staff, 30 min. for others. About 40 per cent. ate in the cafeteria, and 10 per cent. went outside the factory area. The rest ate at or near their place of work or by the water front. Well established social groups always ate in the same place. The percentage of all personnel who bought a complete meal from the cafeteria was only 18, who bought a sandwich lunch 9, and who bought something else 10. The remainder, except perhaps the 10 per cent. who left the factory precincts altogether, ate food brought from home. There seemed to be little seasonal variation in the type of food eaten in the cafeteria, and a rise in prices of 66 per cent., effected gradually, did not decrease the patronage, though an earlier and sudden rise had done so.

Economic, geographical and psychological conditions influencing especially the use or non-use of the cafeteria by the divisions of the staff are analysed in detail. The cafeteria was patronised most by the administrative staff, who had special padded seats, and least by the store staff, who worked furthest away from it and were the least skilled.

It is concluded that "no significant change in the pattern of eating behaviour of the members of this particular factory can be expected without the appropriate re-structuring of the social field". Patronage of the canteen could not be increased simply by changing menus or prices.—E. M. Hume.

5114

SCHULZ, T. **A 'human needs' diet: autumn 1953.** *Bull. Inst. Statistics Oxford*, 1953, 15, 421-435.

The cost of a "human needs" diet, which was 65s. 3d. in April 1953 (Abst. 1042, Vol. 24) had fallen to 64s. 0³d. by the autumn of that year, mainly owing to the seasonal fall in the price of vegetables. Comparison of the autumn diet with Rowntree's "human needs" diet of 1936 (Abst. 1313, Vol. 7) showed a shift in expenditure from meat to milk, and because of this and the addition of Ca to bread and flour, the 1953 diet provided 0.8 g. Ca per male adult equivalent daily, compared with about 0.5 g. in the 1936 diet; the animal protein content of the 2 diets, however, was much the same.

The idea of "human needs" is re-examined in the light of the changed situation due to derationing.

A "simple" diet is described, with less meat but more milk (some of it skimmed condensed milk instead of fresh), legumes and fat, which is claimed to supply "meals reasonably varied and appetising, as well as nutritious" for 56s. weekly, the nutrient intakes being similar to those on the "human needs" diet, except for animal protein. Finally, a diagram is given to illustrate the relation between the cost of the "simple" and "human needs" diets and average working-class incomes, and it is concluded that these diets would be within the reach even of a family on the National Assistance level.—W. M. Deans.

RYER, R. (III), GROSSMAN, M. I., FRIEDEMANN, T. E., BEST, W. R., CONSOLAZIO, C. F., KUHLE, W. J., INSULL, W. (Jr.) and HATCH, F. T. **The effect of vitamin supplementation on soldiers residing in a cold environment. 1. Physical performance and response to cold exposure.** *J. Clin. Nutr.*, 1954, **2**, 97-132. [U.S. Army Med. Nutr. Lab., Denver, Colo.] Spanish summary.

Tests of endurance of cold and high physical activity were made on 86 recruits during January to March 1953 at an altitude of 8300 ft. A capsule, containing 10 mg. vitamin B₁, 10 mg. riboflavin, 100 mg. nicotinic acid, 80 mg. Ca pantothenate, 40 mg. pyridoxine, 2.5 mg. folic acid, 4 µg. vitamin B₁₂ and 300 mg. ascorbic acid, was given 4 times daily to 44 men, and a capsule containing 6 mg. ascorbic acid only to 42 men. Prescribed clothing was worn and at first food providing 4000 Cal. was allowed, but during the last 3 weeks only 2250 Cal. Tests of physical fitness were made at weekly intervals. No significant difference was found between the groups, and no effect of energy restriction could be shown in the last 3 weeks. During the period of low energy intake the effect on rectal temperature of exposure to cold was more marked in the subjects having the small supplement of ascorbic acid than

in those having the full vitamin supplement. The general physical performance of the men was not apparently affected by the energy restriction.

CIANI, G. Consumo di carne e di pesce in provincia di Pescara nell'anno 1951. [The consumption of meat and fish in the province of Pescara during the year 1951.] *Zootec. Vet.*, 1954, 9, 83-96. [Univ. Perugia.]

The consumption of different kinds of meat and of all fish in each of the 46 communes of the province of Pescara in 1951 is tabulated. The mean meat consumption per head ranged in different communes from 2.18 to 19.53 kg., mean for the province 12.2 kg., and that of fish from 0.04 to 8.61 kg., mean for the province 2.5 kg. The highest consumption per head of both meat and fish was in the town of Pescara. The kind of meat principally used differed from one commune to another. When lard, bacon and offals were included pigs were the most important source of meat, but pork as such made up a smaller total than beef. In rural communes about 450 pigs were eaten as sucking pig. Forty per cent. of the pigs were killed in slaughterhouses, the rest for private use.

Of cattle, 4690 were slaughtered in the province and 90 carcasses were imported. Most of those slaughtered were between 12 and 20 months old, with fewer cows and bulls. In the town of Pescara beef consumption on the average was 10.65 kg. per head; 10 communes consumed none, and 21 others less than 200 g. per head.

Sucking lambs and kids weighing 11 or 12 kg. made up 85 per cent. of the sheep and goats killed and 57 per cent. on a liveweight basis. Only in 6 communes were adult sheep slaughtered on a large scale. In 15 communes consumption of mutton was less than 1 kg. per head.

Horseflesh was eaten only in the town of Pescara, where 316 horses were slaughtered. Other sources of meat, i.e., poultry and rabbits, provided 1.8 kg. per head over the whole province, and less than 350 g. in only 3 communes.

Only 9 communes had public slaughterhouses, 4 of recent construction, and hygiene was poor in other places. Only in Pescara was there refrigeration. There were 166 butcher's shops, one for each 1445 people, and 4 communes had none: in 40 communes fish was sold only in the open, in deplorable conditions of hygiene.

The findings are discussed in relation to the mean consumption in the whole country and to economic conditions.—D. Duncan.

DIET IN ETIOLOGY OF DISEASE

METHODS OF ASSESSING STATE OF HEALTH

5127

GREENBERG, B. G. and BRYAN, A. H. **Methodology in the study of physical measurements of school children. 1.** *Human Biol.*, 1951, 23, 160-179. [Univ. N. Carolina, Chapel Hill.]

Physical differences between schoolchildren with different social and economic backgrounds were investigated by measurements of age, weight, height, transverse chest diameter at the level of the xiphoid, bi-iliac diameter, and calf circumference made on boys and girls aged from 72 to 167 months. The use of these measurements to discriminate between white children from 2 schools in North Carolina which serve different socio-economic groups was examined. Data were obtained for 292 children in one school and 154 in the other.

Vol. 24, No. 4

Means and variances for each school were calculated for each measurement for a number of different sub-groups by age. It was decided from these that the most suitable groups were those ranging from 96 to 143 months of age, because the data both for boys and for girls showed distinct and significant differences between the schools. The children in school A from urban families with higher than average incomes were, on the average, from 3 to 3.5 cm. taller and over 8 lb. heavier for their age than those in school B. The adjustments for age were made by the technique of analysis of covariance. On the basis of the variances tables are given of the estimated numbers of measurements which would be required to show certain true differences in height and weight as being significant. The other characteristics measured also showed significant differences between the

schools. The boys in school A appeared to have more muscle mass and subcutaneous fat, as judged by calf circumference, for their age and height than boys in school B, but the effect was insufficient to cause any overall difference in weight for given age and height. For girls, difference in calf circumference was significant only for the youngest, 72 to 107 months, but in this case there was an associated difference in weight even after adjustment for age and height. Neither the chest measurement nor the bi-iliac diameter was found to have any additional value in discriminating between the groups.

It was concluded that a suitable description of the physical characteristics of a group of school-children might be obtained from measurements of weight, height, and calf circumference. As a check on the conclusion, the results were subjected to multiple factor analysis, most often used with psychological data. The findings from this analysis were similar except that the measurement of height appeared to be relatively unimportant, especially for school A, bi-iliac diameter being preferred for several of the sub-groups by age and sex.

5129

ŠKERLJ, B. **Thigh girth as a means for evaluation of nutritional status.** *Human Biol.*, 1953, **25**, 28-31. [Univ. Ljubljana, Yugoslavia.]

Measurements were made during 1939-40 of 311 men of 18 to 23 and of 435 women of 17 to 23 years of age and the correlations of chest, waist and thigh circumferences with each other and with height and weight were calculated. It is concluded that thigh girth measured around the thickest part of the upper third is a simple measure of the development of the subject's soft tissues as a whole.—D. Harvey.

5130

BROŽEK, J. **Thigh girth and nutritional status : a comment.** *Human Biol.*, 1953, **25**, 159-162. [Lab. Physiol. Hyg., Univ. Minnesota, Minneapolis 14.]

In reference to Škerlj's conclusion (see previous Abst.) the thigh measurement is noted as being a complex one of bone, muscle and fat and its high correlation with weight indicates that it will add little to knowledge of the energy aspects of nutritional status.

Data from the Minnesota experiment (Abst. 6279, Vol. 20) are quoted to show that after 24 weeks on a greatly reduced energy intake deviation from the normal was greater for the circumference of the upper arm than for that of the thigh.

BEHNKE, A. R. **The relation of lean body weight to metabolism and some consequent systematizations.** *Ann. New York Acad. Sci.*, 1953, **56**, 1095-1142. [Med. Res. Lab., U.S. Submarine Base, New London, Conn.]

An examination is made of the relation between body measurements and metabolism with special reference to age, height, gross weight and lean body weight (LBW) of 129 American Navy personnel and 25 professional football players. Use is also made of wellknown formulae relating metabolism to body measurements and of standard American data giving mean weights for height at age 25 years. To relate these latter to LBW, the mean percentage of fat is taken as 10 per cent. for men and 15 per cent. for women, at age 25, and is assumed to be independent of height. Estimates are made of the increasing percentages of fat with increasing age for an American population; this increase is suggested to be the reason for the fall in metabolism with ageing, found when metabolism is reported per unit of body surface area. Formulae are derived for the prediction of LBW from metabolism, first when metabolism has been calculated from age, height and weight, and second when it has been measured.

From an exhaustive comparison of formulae for the estimation of body surface area, it is concluded that, for adult males, the area is proportional to a fractional power of weight, of the order of 0.73, or, for a given stature, to a power of the order of 0.55; these findings apply also to boys if weights are related to ages. A study of metabolism formulae indicates that although the metabolic rates of men and women may differ by 10 per cent. when expressed in terms of surface area, they may actually be the same per unit of LBW, for comparable weights.

The wider significance of the work is discussed.

5132

GARN, S. M. **Fat patterning and fat intercorrelations in the adult male.** *Human Biol.*, 1954, **26**, 59-69. [Fels Res. Inst., Antioch Coll., Yellow Springs, Ohio.]

The thickness of the subcutaneous fat was measured in soft-tissue X-ray photographs of 87 white American men from 20 to 69 years old.

The thickest fat deposit measured was over the iliac crest, with an average depth of 18.9 mm. including skin. Then came the deltoid insertion, trochanteric, posterior, medial and lateral leg fat,

N.A. and R., October 1954

lateral and medial arm fat and anterior leg fat, the last only 2.7 mm. including skin. In men weighing less than 74 kg. deltoid fat was the thickest, but in men of 75 kg. or more, iliac fat was thicker. Trochanteric and medial leg fat showed the highest correlations with bodyweight ($r = +0.71$). All 9 measurements were positively and significantly intercorrelated.—D. Duncan.

5133

BERRY, W. T. C., COWIN, P. J. and DAVIES, D. R. **A relationship between body fat and plasma pseudo-cholinesterase.** *Brit. J. Nutrition*, 1954, **8**, 79–82. [Minist. Health, 23 Savile Row, London, W.1.]

The relation of surface fat to plasma cholinesterase was studied in 345 healthy males, 145 adults and groups of 86 and 114 youths in their 17th year. Surface fat was measured as skinfold thickness at 5 sites, and plasma cholinesterase was estimated from blood samples collected on filter paper. The results showed a marked positive relation between body fat and pseudo-cholinesterase, the total correlation coefficient being 0.26, which is highly significant. The relation, which held in each sub-group, was influenced to a slight extent by bodyweight but, on the evidence available for one sub-group, did not in any way depend on energy intake.—M. B. Richards.

GENERAL STUDIES

5136

VERROTTI, M. **Il problema del prematuro; frequenza dei parti prematuri con particolare riferimento al periodo bellico. Analisi delle**

Vol. 24, No. 4

cause. [The problem of the premature infant: frequency of premature births especially in the war period. Analysis of causes.] *Lattante*, 1953, **24**, 449–457. [Ist. Clin. Pediat., Univ. Siena.] English summary.

The number of births registered as premature in the sense of a shortened gestation period was investigated in the commune of Siena in the 15 years 1936–50. The total number of births was 10,799, of which 588 (5.4 per cent.) were premature. The percentage was 3.8 in 1936, 3.9 in 1940, 4.8 in 1941, 5.0 in 1946, 8.9 in 1947, 8.4 in 1948, 6.9 in 1949, and 5.2 in 1950. Possible causes of the increase, including defective nutrition in the war and post-war years, are analysed.—E. M. Hume.

1537

HEWITT, D. and STEWART, A. **The Oxford Child Health Survey: a study of the influence of social and genetic factors on infant weight.** *Human Biol.*, 1952, **24**, 309–319. [Inst. Social Med., Oxford.]

Data on weight at birth and weight increase during the first year of life were analysed for 298 boys and 282 girls in the Oxford Survey. Differences in weight which were associated with parity were found to exist, the children of primiparae tending at birth to be below and at 1 year of age to be above the average for multiparae. In a study of the effect of size of parents, weights and heights of these were obtained for 424 of the babies. Parental weight had a stronger association with infant weight than did parental height; after allowance for the association of weight and height in parents the net correlations were statistically significant.

When these allowances for parity and parental size were made in addition to that for sex, estimated weight differences between groups defined by maternal efficiency, home amenities, social class and sickness experience were considerably reduced. Weight of the infant at birth was measurably affected by bad health in the mother during pregnancy, and weight at 12 months was, by these adjusted standards, less for breast- than for bottle-fed babies.

For another report from the Survey see Abst. 4970, Vol. 24.—D. Harvey.

5138

NEONOLI, A. A. M. **An enquiry into the infant mortality rate in rural areas of Unyamwezi.** *East African Med. J.*, 1954, **31**, 1–12. [Makerere Med. Sch., Uganda.]

The infant is deprived of its mother's milk for the first 2 to 7 days of life, lives in insanitary and unsuitable conditions and is exposed to malaria and other infections from birth.—L. Wills.

5139

SCHWINN, G. Untermässig-Geborene des 2. Weltkrieges. Ihre körperliche und geistige Entwicklung nach klinischer Aufzucht. [**Under-sized infants of the second world war. Their bodily and mental development after being reared in hospital.**] *Ztschr. Kinderheilk.*, 1954, **74**, 507-518. [Kinderklin., Stuttgart.]

Three hundred and sixteen children born in the period 1940-46 who in premature or multiple births had been underweight at birth and had been retained in hospital for about 2½ months until considered healthy, were examined at the age of 6 to 12 years and their bodily and mental development was compared with that of normally born children. They were on the whole of the tall lanky type, 72.8 per cent. being above normal height for their age, but on the average they were underweight for their height. Bodily development in late infancy and early childhood was not appreciably delayed beyond that of normally born children. Thirty-one per cent. showed sequelae of rickets, but marked deformities of skeletal structure were not evident. Estimation of mental development from school performance showed that 6 per cent. were mentally backward, but did not provide any definite relation between birthweight and intelligence. On the whole the results were gratifying, especially in view of the bad external conditions to which the children had been subjected *in utero*, at the time of birth, and in their early years.

SOMESWARA RAO, K., TASKAR, A. D. and RAMANATHAN, M. K. **Nutrition and haemoglobin surveys in children in Nilgiris district.** *Indian J. Med. Res.*, 1954, **42**, 55-75. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

The results are reported of a survey of the nutritional state of 2293 children belonging to poor or lower-middle-class families. The boys were between 2 and 19 and the girls between 2 and 14 years of age as recorded in school registers. At the examination a form was completed which included measurements of height, weight and hip-width, of Hb by Wong's method (*J. Biol. Chem.*, 1928, **77**, 409) with colour comparison in a photo-electric colorimeter, and, in 1084 of the children, of the thickness of subcutaneous tissue at 5 sites. General appearance was assessed by 4 grades, good, fair, poor or very poor, on the basis of height and weight as measured, on amount of subcutaneous tissue and musculature as judged by inspection, on the condition of the skin and mucous membrane, and on the posture and alertness of the child. Other clinical assessments made referred to the conditions of the eyes, mouth, hair and skin, and bones and to the heart size.

Average body measurements and Hb value, with standard deviations are tabulated for the sexes at yearly intervals of age. When allowance was made for the difference in method of recording age no appreciable variation in heights or weights from the findings in an earlier study by Aykroyd and Rajagopal (Abst. 5494, Vol. 6) was noted. As they approached puberty girls lagged behind boys in Hb and, from the fourth year upwards, the Hb of these Indian children was lower than that of British children by amounts which, on the average, were between 0.5 and 2.0 g. per 100 ml. blood.

The incidences are tabulated of 11 signs for sexes and of 10 signs for age. A sex difference was especially noticeable in the greater incidence among boys of folliculosis, defined as "mild perifollicular prominences without keratotic plugs". Xerosis and Bitôt's spots were most frequent between 2 and 5 years; folliculosis was spread almost uniformly over the ages 5 to 15 years; nutritional oedema was seldom seen after 5 years of age but, because of admissions to hospital, the number of cases seen did not accurately measure the incidence of the disease.

The suitability for survey work of the schedule which was followed is discussed and modifications to exclude certain non-nutritional signs, such as "conjunctival folliculosis" [from the Key on p. 73, this appears to be folliculosis of the eye lids] and pigmentation, pyorrhoea and purulent conjunctivitis and to include others of possible nutritional significance, such as cheilosis or koilonychia, are proposed.—D. Harvey.

5141

SZCZYGIŁŁA, A., WOŹNIAK-TORBIĆKA, E., BERGER, S., SZCZYGIŁŁOWA, M., RUDOWSKA-KOPROWSKA, J. and SZKIEŁACZKOŹA, W. Sposób odżywiania się a stan odżywienia wybranej grupy młodzieży. [**Nutrition and nutritional status of a group of young people.**] *Rocz. Państwowego Zakł. Hig.*, 1954, **5**, 1-14. [Z Działu Hig. Żywnienia PZH.] Russian and English summaries.

In a survey made in a state boarding school in the Warsaw district the children were found to be well nourished. Values for nutrients obtained by chemical analysis of the diet tended to be below those calculated from analytical tables, especially for vitamin C. Hb and serum protein were within normal limits but blood carotene was below normal; blood and urinary ascorbic acid values also were subnormal. Suspected clinical signs of vitamin deficiency were found in the following percentages of those examined: vitamin A 1, vitamin C 2, riboflavin 4 and nicotinic acid 8. (From summary.)—D. Harvey.

5142

DUGUID, J. B. **Diet and coronary disease.** *Lancet*, 1954, **266**, 891-895. [Dept. Pathol., Univ. Durham.]

In a general article the morphology, experimental production and etiology of atherosclerosis are discussed, with special reference to experimental cholesterol sclerosis. It is pointed out that there are 2 different forms of atherosclerosis, one arising from mural thrombosis and associated with narrowing of the arteries, the other arising from the deposition of lipids or lipid-bearing cells on the intima and associated with dilatation of the arteries. Either may occur in human subjects, but only the former is important in coronary disease. The evidence of a relation between diet and atherosclerosis in man is discussed. To cause lesions in experimental animals, far more cholesterol is needed than is likely to occur in human diets and the type of change produced is that associated with dilatation. The fatty changes found in the coronary and other arteries may be related to diet, but a direct connection between thrombosis and these changes cannot be demonstrated.—L. Wills.

5143

GOFMAN, J. W., TAMPLIN, A. and STRISOWER, B. **Relation of fat and caloric intake to atherosclerosis.** *J. Amer. Dietetic Assoc.*, 1954, **30**, 317-326. [Donner Lab., Div. Med. Phys., Univ. California, Berkeley.]

In this discussion, based mainly on the authors' published work (see Absts. 686, Vol. 20; 2071, Vol. 21), it is pointed out that no direct measure is available for assessing the degree of atherosclerosis or its rate of development in man. It is assumed for the purposes of the discussion that the tendency of an individual to develop clinical coronary heart disease, termed "coronariness", is directly related to coronary atherogenic potentialities. The best measure of coronariness, obtainable from ultracentrifuging of lipoproteins, is represented by the Atherogenic Index, or A.I. value, given by $(\text{Standard } S_1 0-12 + 1.75 \text{ Standard } S_1 12-400) \div 10$, the Standard S_1 values being in mg. per 100 ml. The probability of developing coronary heart disease rises with increasing A.I. value. Further, high A.I. values are associated with overweight. There is some evidence that raised A.I. values in obese persons may, at least in part, be the result of excessive intake of fat. There is no valid evidence that calories *per se* in a person not losing or gaining weight affect lipoproteins or A.I. values. The possibility that a metabolic disturbance associated with obesity itself leads to raised A.I. values has not been evaluated.

Vol. 24, No. 4

Correction of overweight is likely to be of prophylactic value in obese subjects with high A.I. values, but may have little therapeutic value in established coronary disease.—F. C. Aitken.

5144

SHUMAN, C. R. and WOHL, M. G. **Nutritional aspects of heart failure.** *J. Clin. Nutrit.*, 1954, **2**, 5-10. [Nutrit. Project, Philadelphia Gen. Hosp.] Spanish summary.

5146

BRAS, G., JELLIFFE, D. B. and STUART, K. L. **Veno-occlusive disease of liver with non-portal type of cirrhosis, occurring in Jamaica.** *Arch. Pathol.*, 1954, **57**, 285-300. [Dept. Pathol., Univ. Coll. West Indies.] Etiology uncertain, but ascribed to "bush tea" and poor diet.

5147

SCHETTLER, G. **Ist der sogenannte Greisenbogen der Hornhaut ein Hinweis auf Atherosklerose? [Is so called arcus senilis of the cornea a sign of atherosclerosis?]** *Deutsch. med. Wochenschr.*, 1954, **79**, 915-917. [Med. Klin., Univ. Marburg a.d. Lahn.]

Analysis of the records of 3000 general hospital cases showed that *Arcus lipoides corneae* seldom appeared before the age of 40, that its frequency increased with age, and that it occurred more frequently in men than in women. In patients with definite atherosclerosis it was more frequent than in controls free from vascular disease. From a study of tables showing the frequency of atherosclerosis in persons with and without *Arcus lipoides corneae* it appears that if it is present in men of the age groups 40 to 49, 50 to 59 or 60 to 69, or in women of the group 50 to 59, there is a strong probability of atherosclerosis. *Arcus lipoides corneae* consists predominantly of lipids, chiefly cholesterol, but increase of blood cholesterol cannot be the sole cause of its formation, for the distinct increase of its frequency after the age of 60 is accompanied not by an increase but more often by a decrease of blood cholesterol. In the development of atherosclerosis and also of *Arcus lipoides corneae* some local factor must be concerned.—M. B. Richards.

5148

BERRY, W. T. C. **Myotatic irritability.** *Brit. J. Nutrition*, 1954, **8**, 165-170. [Minist. Health, 23 Savile Row, London, W.1.]

Muscle irritability, shown by local contraction in response to firm tactile stimulation, was found in undernutrition and decreased with abundant feeding (Abst. 1187, Vol. 18). This was re-investigated in 105 men examined in Berlin during the Russian blockade in January and March 1949, and again in October after the food situation had improved (see Abst. 4013, Vol. 21).

Muscle irritability was negatively related to the amount of body fat and was less in October than in the earlier tests. Treatment of 8 subjects with vitamin B₁ did not consistently reduce muscle irritability, in contrast to the report of Taylor and Chhuttani (Abst. 5394, Vol. 19). The sign persisted in 4 curarised subjects and was increased in 3 of them.

It is suggested that flaccidity and the degree to which the muscle can be compressed by the pinch determine the extent of the response. Under-nutrition, vitamin B₁ deficiency and curarisation all lead to soft, easily compressed muscles.

HAGAN, T. L., PASTERNAK, M. and SCHOLZ, G. C. **Waterborne fluorides and mortality.** *Pub. Health Rep., Washington*, 1954, **69**, 450-454. [Div. Dent. Pub. Health, Bur. State Serv., Pub. Health Serv.]

The prevalence of 5 groups of diseases in relation to exposure to F was studied by examination of the adjusted mortality rates in 32 pairs of cities with populations of 10,000 or more in 16 States. In one of each pair, the fluoride city, the F content of the water supply was above 0.70 p.p.m. and in the other, the non-fluoride city, it was below 0.25

p.p.m. Populations in the fluoride cities totalled 892,600 and in the non-fluoride 1,297,500. Geographically the cities were paired as near each other as possible.

Average mortality rates per 100,000 population for fluoride and non-fluoride cities, respectively, were heart disease 354.8 and 357.4, cancer 135.4 and 139.1, intracranial lesions 111.5 and 104.8, nephritis 21.9 and 26.9, cirrhosis of liver 6.6 and 8.2, all causes 1010.6 and 1005.0. The differences between the rates for fluoride and non-fluoride cities were not statistically significant.

Of the 32 pairs of cities the numbers of occasions in which the incidence of the particular disease was higher in the fluoride than in the non-fluoride city were: heart disease 15, cancer 16, intracranial lesions 19, nephritis 13, liver cirrhosis 15.

GELFAND, M. **Kwashiorkor. A description of a case in a breast-fed infant.** *S. African Med. J.*, 1954, **28**, 185-186. [Salisbury Native Hosp., S. Rhodesia.]

Clinical data are given of the occurrence of kwashiorkor in a third child on the breast; 2 earlier cases have been reported by the author (see Absts. 4744, Vol. 16; 1124, Vol. 22). The evidence

N.A. and R., October 1954

of the child's mother was that while breast-feeding her milk flow had been adequate.

The protein deficiency theory of the cause of the disease is briefly discussed. Deficiency of B group vitamins or interference with absorption of these by toxins in maize and other cereals are other possible causes, further study of which is advocated.—D. Harvey.

5158

THOMSON, F. A. **Notes on kwashiorkor in Malaya.** *Trans. Roy. Soc. Trop. Med. Hyg.*, 1954, **48**, 150-152.

In the district of Perak kwashiorkor is the cause of severe chronic ill-health rather than of acute illness. The clinical records of 100 children are summarised; 77 were between 18 months and 4 years of age, the extremes being 3 months and 5 years. The children affected were 84 Malays, 14 Chinese and 2 Indians in a district where the population, per cent., was 12 Malay, 68 Chinese and 20 Indian. Indians use some cow's milk, Chinese little milk but eggs occasionally and fish in fair quantity, Malays little but rice. A taste exists for sweetened powdered or evaporated milk and there is a real need for such foods to be made available in the shops.—D. Harvey.

CHARMOT, G., LINHARD, J., GIUDICELLI, P. and TRAPET, P. **Intérêt clinique des perturbations de l'équilibre protidique en pathologie tropicale. Considérations sur la "dysprotéïnémie africaine". [Clinical significance in tropical pathology of disturbances of protein equilibrium. "African dysproteinaemia".]** *Méd. trop.*, 1953, **13**, 961-976. [Corps de Santé Colonial, Hôp. Coloniaux.]

The methods used are described, and their usefulness and significance are discussed; previous results with the same methods are quoted. A detailed report is given of the results of paper electrophoretic studies, and of 5 flocculation tests, made on serum from healthy and sick Europeans and Africans living in Dakar. For both races, troops living in barracks under similar conditions were taken as normals.

In the African compared with the European, the values for serum proteins, like those of other workers, showed a moderate excess of total proteins with a moderately low albumin fraction, and a marked excess in the γ -globulin fraction, but in 20 per cent. of the 103 Africans examined the values were the same as for the Europeans. In 56 healthy Africans the 5 flocculation tests gave normal results in 12 subjects only; in the remainder the results were abnormal in one or more tests.

Vol. 24, No. 4

The results of similar examinations in patients of both races suffering from jaundice, cirrhosis, fatty liver or amoebic hepatitis are reported in detail; the differences between the races in the results obtained are discussed and the need to make allowance for the initial difference between the serum protein patterns is stressed. From the results it is concluded that necrotic lesions of the liver are associated with high α -globulin and an increase in the intensity of the positive reaction to the plasma formol gel test, that parenchymatous liver lesions are associated with high β -globulin and with a positive reaction to the MacLagan test, and that mesenchymal liver lesions lead to an increase in γ -globulin and a strongly positive reaction to the serum formol gel test.

The results of liver biopsies in 35 Africans with no sign of liver disease are quoted. In 13 of the biopsies the material appeared normal, in 3 there was evidence of a latent precirrhotic condition and in 20 there was some pathological change in the mesenchymal tissue. The intensity of the histological changes was reflected in alteration of the serum protein equilibrium, especially increase in γ -globulin as shown by electrophoresis or the serum formol gel test.—L. Wills.

MARQUES, R. J. **Dermatosis carenciales en cirróticos. [Deficiency dermatitis in cirrhosis of the liver.]** *Rev. española Enferm. Apar. digest. Nutricion*, 1954, **13**, 122-129. [Fac. Cienc. Méd., Pernambuco.] English summary.

Skin lesions resembling those described in pellagra or vitamin A deficiency were observed in 76 per cent. of patients with cirrhosis of the liver, but were rare in other patients from the same environment. Xerosis, hyperkeratosis and glossitis were the most frequent lesions. The feet, legs and elbows were the most common sites for pigmented

dermatosis. Histological study of some skin specimens showed changes resembling those found in vitamin deficiencies. The problem of secondary deficiency in cirrhosis is very briefly discussed.

MARTÍNEZ PÉREZ, F. Acrodinia. Consideraciones etiopathogenicas y terapeuticas. [**Acrodynia. Etiopathology and treatment.** *Rev. española Pediat.*, 1954, **10**, 27-39. [Elda, Alicante.] French, English and German summaries.

Three cases of acrodynia are described which lacked some of the signs considered essential for this condition; such incomplete cases may occur with considerable frequency. One patient showed an excellent response to treatment with BAL (British antilewisite), the antidote for heavy metal poisoning. ACTH and cortisone are recommended for cases that have proved resistant to vitamin B₆ and the other usual treatments. The recognised signs of acrodynia, its pathology and treatment, and the theories of its etiology are discussed.

FLINK, E. B., STUTZMAN, F. L., ANDERSON, A. R., KONIG, T. and FRASER, R. Magnesium deficiency after prolonged parenteral fluid administration and after chronic alcoholism complicated by delirium tremens. *J. Lab. Clin. Med.*, 1954, **43**, 169-183. [Dept. Med., Univ. Minnesota, Minneapolis.]

A non-alcoholic woman given parenteral fluids on account of persistent vomiting developed twitching, gross muscle tremor and choreiform movements, could not talk or eat and appeared to be delirious and disoriented. She was found to have low serum Mg (1.19 m. equiv. per litre). Prompt improvement followed administration of Mg by intramuscular injection of magnesium sulphate solution.

Thirteen chronic alcoholics with tremor and 17 with mild or severe delirium as well, all said to have a bad dietary history [no details] had low serum Mg values, mean 1.40 ± 0.24 compared with 1.91 ± 0.20 m. equiv. per litre in normal

persons, and the worse their condition, the lower the serum Mg. In 20 of 23 treated, good results followed intramuscular injections of a 50 per cent. magnesium sulphate solution, improvement generally being manifest in 24 hr. or less. The amount recommended is 2 g. MgSO₄·7H₂O four times daily for 3 days; then, if needed, 1 g. four times daily for 2 to 4 days more. Case histories are given.

The results are discussed with reference to the literature on Mg deficiency in animals and the possibility of its occurrence in man. It is concluded that Mg deficiency occurs in man more commonly than is generally supposed. Among them, the patients exhibited all the signs observed in Mg-deficient animals, although a single individual might exhibit only a few.—W. M. Deans.

JELLIFFE, D. B. *Ascaris lumbricoides* and malnutrition in tropical children. *Doc. Med. geogr. trop.*, 1953, **5**, 314-320. [Dept. Med., Univ. Coll. W. Indies, Jamaica.]

The nutritional physiology of the roundworm is discussed. The literature shows that in the gut the parasite metabolises 1.4 g. carbohydrate and 0.35 g. protein daily per 100 g. undried parasite, and absorbs and metabolises not only protein, fat and carbohydrate but also vitamins, particularly those of the B complex. A Jamaican child of 4 years, heavily infested with worms, was underdeveloped and underweight and complained of abdominal discomfort. Treatment resulted in the expulsion of 120 adult worms weighing 200 g., and was followed by gain in weight and improvement in amino-acid absorption compared with the values before treatment. The serum proteins rose in 14 days from 5.6 to 6.8 g. per 100 ml.—L. Wills.

SOMESWARA RAO, K., DE, N. K. and SUBBA RAO, D. Investigation of an outbreak of night-blindness in a village near Madras. *Indian J. Med. Res.*, 1953, **41**, 349-357. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

The village was 16 miles west of Madras; data were obtained also from a nearby village where no case of night blindness was reported. The inhabitants of both villages were extremely poor and

N.A. and R., October 1954

illiterate. Cholum (*Sorghum vulgare*) was the main cereal consumed; flesh food and dairy products were not eaten. The diets were deficient in many respects and the average daily Calorie intake was only 1000 per consumption unit. The vitamin A potency of the diet, which was derived chiefly from carotene, was 2600 I.U. daily in families complaining of night blindness, and was actually lower, 1030 I.U., in families with no case of night blindness and not showing evidence of impaired capacity for dark adaptation.

Evaluation of nutritional status included measurement of the capacity for dark adaptation, concentration of Hb and degree of intestinal infestation in 207 people from the first village and 115 from the second. Incidence of anaemia in the first village was high, 34 per cent. having Hb values under 10 g. per 100 ml., compared with 14.8 per cent. in the second village. Impairment of capacity for dark adaptation was associated with the recurrence of anaemia.

In a therapeutic trial 71 patients with impaired capacity for dark adaptation were divided into 3 groups, which received daily from 130 to 260 mg. ferrous Fe, or 1 ml. shark liver oil containing 12,000 I.U. vitamin A, or a placebo. In addition all subjects received supplements to the diet. Considerable improvement in dark adaptation occurred in all groups, the average percentage showing improvement being 83, 100 and 73, respectively.—I. M. Sharman.

ROHMER, A., MICHEL, M., HAARSCHER, A. and LOBSTEIN, A. Deux cas de xérophtalmie chez des nourrissons atteints de dysfonction hépatique, avec lithiase urinaire chez l'un d'eux. Les problèmes de l'avitaminose A. [Two cases of xerophthalmia in infants with disorders of liver function, one of them having urinary calculi. Problems of vitamin A deficiency.] *Pédiatrie*, 1954, 9, 33-39. [Inst. Puériculture Dr. Schneegans.]

Two babies, one of 4 months and one of 3 months, were admitted to hospital with jaundice, in treatment of which they were given skimmed milk.

After about 2 months one was found to have advanced keratomalacia of the right eye. It was given 2 injections of vitamin A but died within a week.

The second child showed early signs of xerophthalmia after 8 days' treatment with partly skimmed milk; it had already received 2 injections of vitamin A when the eye condition was noticed. The eyes improved but 2 months later it developed pyelitis, and passed a number of stones in the urine. It gradually recovered.

It is recommended as routine to give vitamin A to all infants with jaundice.—E. M. Hume.

5172

LAHIRI, K. D. and SCANDRETT, F. J. Low blood vitamin-A levels in dermatology. *Indian Med. Gaz.*, 1954, 89, 31-32. [Med. Coll., Calcutta.]

Vitamin A and carotene were estimated in the blood of patients suffering from skin diseases and in normal healthy subjects. Average values for vitamin A in the blood serum of 9 subjects with ichthyosis and of 15 with nummular eczema were only 131.0 and 115.6 I.U. per 100 ml., respectively, compared with 187.0 for 114 healthy persons. Corresponding values for carotene were 73.3, 59.0 and 69.0 I.U. per 100 ml. Estimations were made also for 16 patients with Besnier's prurigo, 7 with neurodermatitis and 7 with alopecia areata, but the values were within the normal range, the average values being 195.0, 190.0 and 175.0 I.U. vitamin A per 100 ml., respectively. It is claimed that the results provide a basis for relating the lesion in ichthyosis and nummular eczema to deficiency of vitamin A.—I. M. Sharman.

5173

LAHIRI, K. D. and SCANDRETT, F. J. Vitamin A in acne vulgaris. *J. Indian Med. Assoc.*, 1954, 23, 247-249. [Dept. Med. Skin. Dis., Med. Coll., Calcutta.]

Seventy-five patients with acne, who had not previously responded to other forms of treatment, were given 100,000 I.U. vitamin A daily by mouth. Of 30 in whom the principal lesion consisted of papules and pustules on the face, with comedones and oiliness, all were cured after 2½ months. Twenty others with the lesions on the back and face, and 10 with lesions on the face and chest, were completely cured after treatment for 3 months. Ten with cysts healed after 5½ months. The five remaining very resistant patients had cysts; they had been previously treated by routine methods for 4 years and relapsed from 3 to 4 times yearly, but were cured after treatment for 6 months with vitamin A. No evidence of toxicity was seen.

Estimations of carotene and vitamin A in the blood of acne patients not given vitamin A gave average values of 59.4 and 175.1 [presumably I.U. per 100 ml.]. Corresponding values for normal males are reported as 65.7 and 200.3 and for normal females as 71.6 and 174.7, respectively. Serum vitamin A values in the normal subjects rose to a value about three times the fasting value 6 hr. after a test dose of 100,000 I.U. vitamin A, and returned to about the original fasting value

after 24 hr. In the acne patients the peak values were reached also in 6 hr., but the rise was much smaller. The subsequent decline in the acne patients was much slower than in the normal subjects.

The excretion of 17-ketosteroids in the urine was measured in 2 of the male acne patients and was found to fall from about 30 mg. daily before treatment to about 10 mg. daily after 6 months' treatment with vitamin A. It is suggested that presence of acne is probably related to the patient's endocrine status by which defective utilisation of vitamin A may be promoted.—I. M. Sharman.

5174

KLEINE, H. O. Vitamin-A-Therapie bei prämenstruellen nervösen Beschwerden. [**Vitamin A treatment of premenstrual nervous disturbances.**] *Deutsch. med. Wochenschr.*, 1954, **79**, 879-880. [Städt. Frauenklin., Ludwigshafen a. Rh.]

In 100 patients with premenstrual nervous disturbances, as shown by irritability, quarrelsomeness, emotional instability and anxiety, daily doses of 50,000 I.U. vitamin A, given during the second half of the menstrual cycle, were often beneficial. The vitamin is thought to act by counteracting the action of thyroxine produced under the influence of progesterone.—T. Moore.

STURM, W. Zur Behandlung deformierender Gelenkerkrankungen mit Tokopherol. [**Treatment of deforming joint diseases with tocopherol.**] *Ztschr. ges. inn. Med.*, 1953, **8**, 1138-1141. [Inn. Abt., Krankenhaus Küchwald, Karl Marx-Stadt.]

The joint-deformities studied were of the rheumatoid type, defined as collagenoses. Patients were selected in whom the process had not existed for more than 2 years. They were treated for at least 6 weeks with 100 mg. mixed tocopherols from wheat germ oil (Tokopharm-forde, Pharmasan), given orally 3 times a day. Local treatment to promote hyperaemia in affected joints was part of the treatment. Observations have been

made for 2 years, and the results are considered favourable for the use of tocopherol as an auxiliary treatment. No quantitative report is made.

5177

DAHL, O. **The treatment of plastic induration of the penis (Peyronie's disease).** *Acta radiol.*, 1954, **41**, 290-301. [Radiumhemmet, Stockholm.] German and French summaries.

Eighteen patients aged from 20 to 70 years, with induration of the penis, were treated with 300 mg. tocopherol daily for several months. Pain on erection was cured in 6, and decreased in 4, of the 13 patients who originally had this symptom. Penile curvature was cured in 2 and decreased in 4 out of 17 patients. Penile plaques, which were seen in all the patients, disappeared in 3 and decreased in 7. Experience had shown that in the absence of treatment the lesions did not improve. About the same degree of success was obtained in a larger group of patients who were treated with radium. A few who had failed to respond to radium were improved by tocopherol. The results obtained by giving vitamin E to 22 patients with Dupuytren's contracture of the hand, which sometimes accompanies induration of the penis, were not encouraging.—T. Moore.

MEYER, F. L'influence de l'aneurine-pyrophosphate sur le taux d'acide pyruvique dans le sang. [**Effect of vitamin B₁ pyrophosphate on the blood pyruvic acid value.**] *C.R. Soc. Biol.*, 1953, **147**, 1901-1903. [Hôp. de la Pitié, Paris.]

Diabetic subjects whose diet provided 2500 Cal. daily fasted for 14 hr. and then received 12 units of insulin intravenously. Blood sugar and pyruvic acid were estimated at half-hour intervals for 4 hr. The procedure was repeated on the third day, while on the second and fourth the subjects received their usual treatment. On the fifth day procedure was as for the first day except that 1 hr. after injection of insulin, 150 mg. vitamin B₁

N.A. and R., October 1954

pyrophosphate in 5 ml. buffer at pH 7.3 were given intravenously.

The blood pyruvic acid value ranged normally from 0.5 to 1.1 mg. per 100 ml. In the 2 hr. after injection of insulin it rose. The increase was not diminished by administration of vitamin B₁ pyrophosphate and in some subjects it was increased. It is concluded that the blood sugar value and its response to insulin are not related to the pyruvic acid value.—V. R. Jackson.

5181

BARBIERI, L. L., FRANCO, T. and PARENTI, G. Azione della cocarbossilasi sull'elettrocardiogramma e sulla tachicardia da sforzo. [Effect of cocarboxylase on the electrocardiogram and on tachycardia of effort.] *Acta vitaminol.*, 1954, 8, 65-72. [Ist. Clin. Med. Terap. Med., Univ. Bologna.] French, English, German and Spanish summaries.

An electrocardiogram was taken from 10 healthy young persons and from 10 with valvular heart disease, moderately well compensated, when at rest and after an exercise test with ascent and descent of 2 steps. The test was made with and without previous intravenous administration of 50 mg. cocarboxylase. The most important result was that administration of cocarboxylase reduced the mean pulse rate especially after exercise in both sets of subjects, though this was not true for every individual. The mean value for the QT interval was reduced after exercise in the heart patients unless cocarboxylase was given; in the normal subjects there was no effect. The RS and T voltages were increased after exercise when cocarboxylase had been given.—E. M. Hume.

5182

SOLOV'eva, E. J. and CHRUSTAL'eva, V. P. Nekotorye dannye o soderzhanii tiamina v zhenskoi moloke. [Some values for the vitamin B₁ content of human milk.] *Vop. Pitan.*, 1954, 13, No. 2, 16-20. [Gosud. Kontrol. Vitamin. Stants., Minist. Zdravoochran. SSR, Moscow.]

In specimens of breast milk from 37 women, vitamin B₁ was estimated by the thiochrome method after enzymic hydrolysis. The investigations were continued for a year in view of the possibility of seasonal change. The average for the whole period was 21.99 ± 0.48 μ g. per cent. with the majority of values between 18 and 25 μ g. Specimens analysed during the autumn gave an average significantly higher than at other seasons. The values are above many found in the literature; the criteria of normality in this respect are inadequately established. Some conditions which may modify the vitamin B₁ requirement of the infant are discussed.—D. W. Taylor.

Vol. 24, No. 4

5183

CITRON, K. M. and KNOX, R. The uptake of thiamine by a strain of *Staphylococcus aureus* from the duodenum of a case of polyneuritis. *J. Gen. Microbiol.*, 1954, 10, 482-490. [Dept. Bacteriol., Guy's Hosp. Med. Sch., London.]

A strain of *Staphylococcus aureus* was obtained from an elderly polyneuritic patient with steatorrhoea, achlorhydria and macrocytic anaemia, and with deranged pyruvic acid metabolism suggestive of vitamin B₁ deficiency.

The organism was shown to remove vitamin B₁ from culture solution, or to destroy it, and strains of Oxford staphylococcus, *Bacterium coli* and *Proteus vulgaris* were found having the same capacity. It is suggested that a heavy infection might cause clinical deficiency.—V. R. Jackson.

JIMÉNEZ DÍAZ, C., ALÉS, J. M. and VIVANCO, F. La acción simbiótica de la flora microbiana intestinal. (Estudios sobre la síntesis de ácido nicotínico, piridoxina, ácido fólico y vitamina B₁₂ por la flora microbiana entérica.) [The symbiotic action of the intestinal microbial flora. Studies on the synthesis of nicotinic acid, pyridoxine, folic acid and vitamin B₁₂ by the intestinal microbial flora.] *Rev. clín. española*, 1953, **51**, 294-305. [Inst. Invest. Méd., Univ. Madrid.] English, German and French summaries.

Nicotinic acid, pyridoxine, folic acid and vitamin B₁₂ were estimated microbiologically in faeces from 4 normal subjects and 12 patients with various diseases. In the normal subjects the amounts of all vitamins per g. dry weight were similar, but wide variations were found in patients with enteritis, coeliac disease, pellagra and pernicious anaemia, and the values were much lower than in normal faeces. Cultures of faeces in media lacking nicotinic acid, folic acid or vitamin B₁₂ were analysed for their content of B vitamins, and the types of bacteria present were recorded. In faeces from patients with diseases of the gastrointestinal tract there appeared to be competition between bacteria which synthesised and bacteria which consumed the B vitamins. Removal of bacteria which consumed the vitamins permitted normal synthesis. In 2 subjects given terramycin a great decrease in excretion of all B vitamins occurred. The literature on the synthesis and destruction of B vitamins by many bacteria is reviewed and the findings are summarised in a table. The importance of the symbiotic relationships of intestinal bacteria is discussed with reference to the origin of vitamin deficiencies associated with certain diseases.—A. M. Copping.

5189

IMANAGA, H., HOSHIKAWA, S. and ITOI, J. Riboflavin content of human liver. *Nagoya J. Med. Sci.*, 1953, **16**, 212-217. [2. Dept. Surg., Sch. Med., Univ. Nagoya.]

Riboflavin was estimated fluorimetrically in samples of liver from 59 male and female subjects undergoing laparotomy. In those with clinically normal liver function the content of riboflavin was from 2445 to 3310, average 2806, μ g. per 100 g. fresh tissue. Values were slightly less in those with mildly impaired function. In subjects with greatly impaired liver function, in most of them through cancer of the stomach, pancreas or liver, the values were much lower, as low as 900 μ g. per 100 g. in a subject with carcinoma of the liver.

The proportion of free to esterified riboflavin was not much affected.—V. R. Jackson.

5190

ANNONI, G. and LONGARETTI, A. L'azione dell'acido pantotenico sul metabolismo basale. [Effect of pantothenic acid on basal metabolism.] L'azione dell'acido pantotenico sull sistema neurovegetativo studiata con la prova di Breitman. [Effect of pantothenic acid on the neurovegetative system, studied by Breitman's test.] *Acta vitaminol.*, 1954, **8**, 81-82; 83-84. [Osp. Civile G. Fornaroli, Magneta.] French, English, German and Spanish summaries.

Basal metabolism was estimated in 12 patients with moderate hyperthyroidism before and 1 hr. and 1, 3 and 5 days after intravenous administration of 1 g. pantothenic acid alcohol (pantenolo-Bepanten) daily. All the patients except 3 showed within the first hour some reduction of the B.M.R. which remained low to the end of the observation period. Of the 3 exceptions, 2 showed a fall after a day. Only one showed a rise. There was a certain improvement also in the patient's condition.

Breitman's test is based on measuring the areas of the reaction to histamine and adrenaline injected separately into the skin. The test was made on 11 subjects treated with pantothenic acid just as in the foregoing experiment. The areas of both sites of injection tended to be reduced by treatment with pantothenic acid, and the result is interpreted as evidence of a regulating action by pantothenic acid on the sympathetic and parasympathetic nervous systems.—E. M. Hume.

5191

CASASSA, P. M. Il pantenolo nel trattamento della stipsi cronica nei vecchi. [Pantothenic acid alcohol in the treatment of chronic constipation in the aged.] *Acta gerontol.*, 1953, **3**, No. 5-6, 15-22. [Ist. Clin. Med., Univ. Turin.] French and English summaries.

Fourteen patients aged from 68 to 91 years with obstinate constipation were treated with pantothenic acid alcohol (pantenolo-Bepanten, Roche), from 200 to 500 mg. daily given parenterally and sometimes orally later. In most of the patients, after injection of Bepanten, passage of gas and peristalsis quickly ensued, followed by satisfactory evacuation of the bowels. The effect did not usually decrease if treatment was maintained, and continued for a time after treatment was stopped. From 2 to 6 daily injections of 500 mg. followed by a daily oral dose of from 200 to 400 mg. is the dosage recommended.—E. M. Hume.

SUÁREZ, R. M., SUÁREZ, R. M. (Jr.), BUSÓ, R. and SABATER, J. **The effect of orally administered folinic acid in the treatment of tropical sprue.** *Blood, J. Hematol.*, 1954, **9**, 489-495. [Mimiya Hosp., Santurce, Puerto Rico.] Interlingua summary.

After an initial observation period with no treatment 5 patients with acute sprue were treated with folinic acid as calcium leucovorin by mouth. Four responded both clinically and haematologically to 15 mg. three times daily; the nature of the response was unaffected by the presence or absence of free HCl in the gastric juice. Two showed a secondary reticulocyte rise when the folinic acid was replaced by the same dose of folic acid. The fifth case responded poorly to all treatment.

L. Wills.

ARUFFO, B. **Relations fonctionnelles entre la vitamine B₁₂ et l'acide folique en rapport avec la pathogénèse des anémies perniciosuses.** [Functional relation between vitamin B₁₂ and folic acid in relation to the pathogenesis of pernicious anaemias.] *Schweiz. med. Wochenschr.*, 1953, **83**, 1089-1092. [Milan.]

Vol. 24, No. 4

A short review article deals with the relation of the two vitamins to one another, and with their action on oxidase systems and in the synthesis of nucleosides and nucleic acid. The different types of megaloblastic anaemia are considered to be caused by deficiency of one or both of the vitamins. The nature of the deficiency in the different types of anaemia is discussed.—L. Wills.

HAENEL, U. **Die Wirkungsweise der oralen Perniciosatherapie mit Vitamin B₁₂ und Folsäure.** [Mode of action in oral treatment of pernicious anaemia with vitamin B₁₂ and folic acid.] *Schweiz. med. Wochenschr.*, 1953, **83**, 1029-1031 (with discussion 1031). [Med. Abt., Städt. Krankenanst., Mannheim.]

The finding is confirmed that folic acid and vitamin B₁₂, given together by mouth in doses shown previously to be completely inactive when given separately by mouth, will produce a haematological response. It was argued that the action could not be a simple summation effect but was more probably due to interrelated action in the synthesis of nucleic acids. In support of the view an untreated patient with pernicious anaemia was given daily for 5 days 60 mg. each of pure adenine, guanine and hypoxanthine, isolated from ribose-nucleic acid. As no reticulocyte rise occurred 15 µg. vitamin B₁₂, given orally, was added to the daily dose. After 7 days' combined treatment there was a reticulocyte crisis followed by a rise in the red cell count and Hb value. To exclude any intrinsic-factor-like action of folic acid another untreated patient received daily 0.5 mg. folic acid parenterally for 6 days; there was no reticulocyte response. The same dose was continued and at the same time 15 µg. vitamin B₁₂ were given by mouth daily; there was a reticulocyte crisis on the 7th day of combined treatment, followed by a rise in the red cell count and Hb value.—L. Wills.

CARTAGENOVA, L. **Contributo alla conoscenza delle cosiddette anemie perniciosiformi (a megalociti) del lattante.** [The so-called pernicious-like (macrocytic) anaemias in infants.] *Lattante*, 1953, **24**, 856-859. [Ist. Giannina Gaslini, Genoa.] English summary.

The occurrence is recorded of 2 cases of the pernicious-like anaemia of infants, a girl of 12

months and a boy of 13 months. They were from families in very poor and unhygienic urban circumstances, and the etiology was deemed to be nutritional. After 2 months' treatment with liver extract and vitamin B₁₂, their condition was satisfactory.—E. M. Hume.

HEINRICH, H. C. Die biochemischen Grundlagen der Diagnostik und Therapie der Vitamin B₁₂-Mangelzustände (B₁₂-Hypo- und Avitaminosen) des Menschen und der Haustiere. 2. Untersuchungen zum Vitamin B₁₂-Stoffwechsel des Menschen während der Gravidität und Lactation. [Biochemical basis for the diagnosis and treatment of vitamin B₁₂ deficiency states, partial and complete, in human beings and domestic animals. 2. Vitamin B₁₂ metabolism of human subjects during pregnancy and lactation.] *Klin. Wochenschr.*, 1954, 32, 205-209. [Physiol. Chem. Inst., Univ. Hamburg.]

Results from the literature and from the present series showed that during pregnancy and lactation the mean value for total vitamin B₁₂ in the serum was 183, with range from 3.6 to 310, $\mu\text{g.}$ per ml. compared with a mean value for healthy non-pregnant subjects of 238 with range from 62 to 460. In the series studied [no number given] 20 per cent. showed a biochemical deficiency of vitamin B₁₂, their mean value being 35 with range from 3.6 to 50, which are values near those of patients with pernicious anaemia. The pregnant subjects were all apparently normal. Tests on the colostrum and breast milk showed that, as in cows and ewes, of which the colostrum and milk contain far more vitamin B₁₂ than human colostrum and milk, the colostrum contained much

more of the vitamin than did the milk. There was more of the vitamin in the milk of mothers of full-term infants than in that of mothers of premature infants.

After intramuscular injection of 30 $\mu\text{g.}$ vitamin B₁₂ there was retention of the vitamin and an increased excretion in both urine and milk. In pregnant and lactating women with low serum values for total vitamin B₁₂, a single oral dose of 30 $\mu\text{g.}$ of the vitamin led to increased urinary excretion and a steady rise in the serum values, showing that absorption of the vitamin was adequate; addition of intrinsic factor led to greater urinary loss and a more rapid rise to normal of the serum values; excretion in the milk increased also. The vitamin B₁₂ requirement of pregnant and lactating women was calculated to be from 5 to 10 $\mu\text{g.}$ daily, which are amounts above the usual dietary intake. For treatment of patients with low serum values an oral preparation containing both vitamin B₁₂ and intrinsic factor is advised.—L. Wills.

5205

PITNEY, W. R. and BEARD, M. F. **Serum and urine concentrations of vitamin B₁₂ following oral administration of the vitamin.** *J. Clin. Nutrit.*, 1954, 2, 89-96. [Div. Haematol., Sch. Med., Univ. Louisville, Ky.] Spanish summary.

Vitamin B₁₂ was estimated with *Euglena gracilis* in blood serum and urine of normal subjects, and of patients with pernicious anaemia in relapse, before and after a large oral dose of vitamin B₁₂. With a dose of 1000 $\mu\text{g.}$ no significant rise in vitamin B₁₂ was detected in the serum, but an increase occurred after a dose of 5000 $\mu\text{g.}$ in both normal and anaemic subjects. In the serum, the vitamin was in bound form, which probably accounted for the very small increase in the urine after a large oral dose. In patients with pernicious anaemia the extent of the haematological response and the amount of vitamin B₁₂ in the serum were related.—A. M. Copping.

5206

KILLANDER, A. and VAHLQUIST, B. B₁₂-Vitamin-koncentrationen i serum från fullgångna och prematurt födda barn. [Concentration of vitamin B₁₂ in the serum of full-term and premature infants.] *Nord. Med.*, 1954, 51, 777-779. [Barnklin., Akad. Sjukhuset, Uppsala.] English summary.

Vitamin B₁₂ was estimated with *Euglena gracilis* in the blood of 12 full-term infants 1 to 10 days old, mean birthweight 3540 g., receiving only breast milk, of 12 premature infants, 6 to 83 days old, mean birthweight 1700 g., fed on breast milk with supplements of citrated milk, Fe and vitamins

A and D, and of 11 infants [not further described] where samples were taken of cord blood and maternal venous blood at birth.

If from 0.10 to 0.72 μg . per ml. serum is taken as the range of normal adult values, all but 2 of the first 24 sera gave values within normal limits; the 2 exceptions were well above, for no known reason. In the 11 with maternal values also, the cord blood in every case contained more vitamin B₁₂ than the maternal. No relation was found between vitamin B₁₂ values in serum and Hb, and none to the type of feeding or supplements given.

ESTRADA, S. C., LANG, C. A. and CHOW, B. F. **The application of vitamin B₁₂ tolerance tests to American and Mexican subjects.** *J. Lab. Clin. Med.*, 1954, **43**, 406-410. [E. R. Squibb and Sons, Mexico, D.F.]

The urinary excretion of vitamin B₁₂ was measured with *Lactobacillus leichmannii* during 8 hr. after parenteral administration of a single dose of 20, 30, 40, 50 or 65 μg . vitamin B₁₂ to 51 Mexican subjects aged from 18 to 39 in Mexico City and to 47 American subjects aged from 24 to 47 in Baltimore. With all the amounts the Mexicans excreted significantly less than the Americans. The findings are attributed to differences in the dietary intake of vitamin B₁₂. The amounts in the Mexican diet were less than 0.2 μg . a week and those in the American diet about 1 to 5 μg . a day.—A. M. Copping.

GRAHAM, R. M. and RHEAULT, M. H. **Characteristic cellular changes in epithelial cells in pernicious anemia.** *J. Lab. Clin. Med.*, 1954, **43**, 235-245. [Vincent Mem. Hosp., Boston, Mass.]

Detached squamous and columnar epithelial cells, most of which had been swallowed, were obtained by gastric suction from 20 patients with relapsed pernicious anaemia, 21 patients with pernicious anaemia in remission, 7 patients with iron deficiency or haemorrhagic anaemia, some of whom had free HCl in the gastric contents, and 10 normal subjects. In the patients with relapsed pernicious anaemia both squamous and columnar epithelial cells showed an increase in the size of cell and nucleus compared with those of any of the other subjects. Price-Jones curves confirmed the increase. It is suggested that the cellular changes resulted from a failure of maturation caused by deficiency of the extrinsic factor.

MONTO, R. W. and REBUCK, J. W. **Nasal instillation and inhalation of crystalline vitamin B₁₂ in pernicious anemia.** *Arch. Int. Med.*, 1954, **93**, 219-230. [Div. Haematol., Henry Ford Hosp., Detroit, Mich.]

In 12 patients with pernicious anaemia in relapse a single nasal instillation or inhalation of 100 μg . crystalline vitamin B₁₂ caused a maximum response, but one of 15 μg . by the same route had only submaximum results; a daily dose of 15 μg . produced a maximum response. In 20 patients in remission the maintenance dose was as low as 15 μg . every other week. No toxic effect or local reaction was seen. Vitamin B₁₂ appeared in the urine after nasal administration.—L. Wills.

5216

CHALMERS, J. N. M. and HALL, Z. M. **Treatment of pernicious anaemia with oral vitamin B₁₂ without known source of intrinsic factor.** *Brit. Med. J.*, 1954, i, 1179-1181. [Dept. Haematol., St. George's Hosp., London.]

When a single oral dose of from 2000 to 9000 μ g. vitamin B₁₂ was given, a satisfactory initial haematological and clinical response was obtained in 4 patients with pernicious anaemia in relapse, and in 2 with megaloblastic anaemia after gastrectomy; one similar patient given 1000 μ g. showed a suboptimum response. The patients were fasting and no food or drink was taken for 4 hr. after the vitamin was given. In 7 further patients with pernicious anaemia, a satisfactory response was obtained by the use of a daily oral dose of 50 μ g. vitamin B₁₂ taken at midnight; no food was allowed for 6 hr. before and after. One patient was brought into and maintained in remission for 18 months on a daily oral dose of 50 μ g. taken on retiring. When taken with food the vitamin was much less effective than when taken fasting. Tween 20 had no apparent effect on absorption.

L. Wills.

5217

ROSS, G. I. M., MOLLIN, D. L., COX, E. V. and UNGLEY, C. C. **Hematologic responses and concentration of vitamin B₁₂ in serum and urine following oral administration of vitamin B₁₂ without intrinsic factor.** *Blood, J. Hematol.*, 1954, 9, 473-488. [Postgrad. Med. Sch., London.] Interlingua summary.

Vitamin B₁₂ was estimated biologically with *Euglena gracilis* var. *bacillaris* in the serum and urine before and after test doses of 500, 1000 or 3000 μ g. of the vitamin by mouth. There were 38 patients with pernicious anaemia in relapse, 2 with megaloblastic anaemia after partial gastrectomy and 4 normal subjects.

The sensitivity and specificity of the method are not such as to make it possible to distinguish patients with pernicious anaemia in relapse from normal subjects. Evidence of absorption of vitamin B₁₂ from the rectum suggested that absorption does not require the presence of intrinsic factor. Details of serum and urine concentration and of haematological response are presented in tables and graphs.—L. Wills.

MEULENGRACHT, E. **Treatment of pernicious anaemia with very small quantities of pyloric mucosa and vitamin B₁₂.** *Brit. Med. J.*, 1954, i, 838-841. [Med. Dept. B, Bispebjerg Hosp., Copenhagen.]

The site of production of intrinsic factor having been shown to be the pyloric mucosa (Absts. 896,

3501, Vol. 23), a preparation of dried pig pyloric mucosa was tested on patients with untreated pernicious anaemia. Minute amounts, 0.3 to 0.6 g. daily by mouth, produced only a slight and inadequate reaction in 9 of 12 patients, but the same amounts with 5 or 10 μ g. pure vitamin B₁₂ gave a full reticulocyte crisis and rise of both Hb and red cells. A proprietary preparation [called Cycoplex 7 times and Cycoplex 4 times] with 0.05 g. dried pyloric mucosa and 5 μ g. vitamin B₁₂ per capsule, 3 daily, was similarly effective in hospital practice. It remained to be shown whether there was any difference in effect when the treatment was given with meals or between meals.—I. Leitch.

CALLENDER, S., TURNBULL, A. and WAKISAKA, G. **Intrinsic factor after total gastrectomy.** *Clin. Sci.*, 1954, 13, 221-224. [Nuffield Dept. Clin. Med., Radcliffe Infirmary, Oxford.]

In 8 patients who had undergone total gastrectomy the secretion of intrinsic factor was estimated indirectly from the amount of radio-activity appearing in the faeces after a test dose of vitamin B₁₂ labelled with ⁶⁰Co. In 7 patients the excretion was over 80 per cent. and in 1 patient it was 67 and 66 per cent. in 2 tests. The values are of the same order as those found in patients with pernicious anaemia. When radio-active vitamin B₁₂ was given with 10 mg. of a dried concentrated extract of pig gastric mucosa as source of intrinsic factor, the excretion fell to 57 per cent. or less in the 7 patients and to 29 per cent. in the one. The findings are considered to support the view that in man intrinsic factor is produced only in the stomach. The smaller excretion in the one patient was thought probably due to incomplete removal of stomach tissue.—L. Wills.

5221

YAMAMOTO, R. S. and CHOW, B. F. **A rapid method for the determination of B₁₂ binding power in the gastric juice.** *J. Lab. Clin. Med.*, 1954, 43, 316-320. [Dept. Biochem., Sch. Hyg., Johns Hopkins Univ., Baltimore, Md.]

Vitamin B₁₂ was found to combine with a substance or substances in gastric juice in such a way that it could not be adsorbed by resting cells of *Lactobacillus leichmannii*. The observation was utilised to measure the vitamin-B₁₂-binding capacity of gastric juice. From adult patients with

pernicious anaemia, the gastric juice had a lower binding capacity than from adolescent patients or from normal adults. There appeared to be an association between high gastric acidity and low capacity for binding vitamin B₁₂ in normal subjects over 60 years of age, but not in subjects aged from 25 to 45. The gastric juice of old people with achlorhydria had normal ability to bind vitamin B₁₂.—A. M. Copping.

5222

PITNEY, W. R., BEARD, M. F. and VAN LOON, E. J. **Observations on the bound form of vitamin B₁₂ in human serum.** *J. Biol. Chem.*, 1954, **207**, 143–152. [Sect. Haematol., Dept. Med., Sch. Med., Univ. Louisville, Ky.]

The concentration of vitamin B₁₂ estimated with *Euglena gracilis* varied from 122 to 460, mean 195, $\mu\text{g.}$ per ml. in 13 normal sera, in 10 of which all the vitamin was present in a bound form. When 1000 $\mu\text{g.}$ crystalline vitamin B₁₂ per ml. were added to serum *in vitro* relatively small amounts became bound, the mean concentration of the bound form being increased from 178 to 336 $\mu\text{g.}$ per ml. Paper strip electrophoresis was used to identify the serum protein fractions containing bound vitamin B₁₂. Almost all the activity was found in the α -globulin fractions, very little in the other globulins, and none in the albumin. In addition, the vitamin B₁₂ bound *in vitro* was mainly recovered from the α -globulin fractions.

Investigation of 20 sera from patients with different diseases other than anaemia gave a range of total vitamin B₁₂ from 50 to 540, mean 193, $\mu\text{g.}$ per ml.; the values thus corresponded closely with those for normal sera. The nature of the substance binding vitamin B₁₂ and the importance of this function of certain fractions of the serum proteins are discussed.—A. M. Copping.

FEUILLEN, Y. M. Iron metabolism in infants. 2. Absorption of dietary iron.

FEUILLEN, Y. M. and LAMBRECHTS, A. 3. The influence of vitamin C on the absorption of iron. *Acta paediat.*, 1954, **43**, 181-187; 188-191. [Clin. Policlin. Maladies de l'Enfance, Univ. Liège.] French, German and Spanish summaries.

For part 1, see Abst. 674, Vol. 23.

2. Thirty-seven Fe balance experiments were made on 19 full-term infants at ages ranging from 15 days to 9 months. The artificial diets were a mixture of milk, water, sucrose, dextrimaltose or starch, with or without vegetable soup; buttermilk and acid milk; commercial acid milk; or commercial buttermilk. The Fe intake ranged from 0.3 to 1.08 (mean 0.37) mg. per kg. bodyweight daily. The average retention was 0.19 (range 0.0 to 0.56) mg. per kg. bodyweight daily, or 53 per cent. of the mean intake. There were two zero balances and none negative. In 2 experiments with infants fed on breast milk the intakes were 0.08 and 0.12 mg. and the retentions 0.04 and 0.09 mg. or 48 and 78 per cent.

3. Fourteen Fe balance studies with 7 infants aged from 4 to 7½ months on a normal diet showed that the addition of 100 mg. vitamin C daily had no effect on the absorption or retention of Fe.

MIKI, T., MACHII, S., UNO, C., FUKUDA, M., HASHIMOTO, M., OURA, T., IWASAKI, H., MATSUMOTO, K., GOSHI, N., OSE, T. and SHIMOYAMA, M. [On infantile rickets in cities and villages around Osaka.] 1. *J. Osaka City Med. Center.*, 1953, **2**, 309-315 (English summary, p. 347). [Med. Affairs Sect., Osaka Prefecture, Osaka City.]

Of 843 infants aged between 2 and 6 months, born in winter, and living in the environs of Osaka City, 10.2 per cent. were found rachitic from X-ray pictures of the hand. The incidence is analysed according to district, sex, system of feeding and age. Administration of from 200 to 500 I.U. vitamin D daily in fortified powdered milk did not prevent the occurrence of the disease. Respiratory infections were more common among rachitic than non-rachitic infants. (From summary.)

ZWEYMÜLLER, E. and RÖSSLER, H. Chronische vitamin-D-resistente Rachitis mit Nephrocalcinose. [Chronic rickets resistant to vitamin D with calcification of the kidney.] *Helv. paediat. Acta*, 1954, **9**, 28-42. [Kinderklin., Univ. Innsbruck.] French, Italian and English summaries.

Rickets had persisted in a girl of 16½ years since infancy in spite of treatment with cod liver oil and vitamin D₂. There was a calcified lesion of the kidneys, visible radiographically, which gave rise to acidosis and high blood chloride. Treatment with an alkaline mixture and dihydrotachysterol restored the X-ray picture of the skeleton to normal apart from deformities.—E. M. Hume.

5237

RUPP, W. and SWOBODA, W. Clearance-Untersuchungen bei Vitamin D-resistenter Rachitis. [Clearance tests in vitamin-D-resistant rickets.] *Monatsschr. Kinderheilk.*, 1954, **102**, 173-175. [Vienna.]

Inorganic P was estimated in the blood serum and urine of 2 normal subjects and 3 patients with resistant rickets before and after intravenous injection of phosphate with or without an aqueous solution of vitamin D₂. In the patients, the amounts of PO₄ excreted in the urine on the normal diet was within the higher range of normal, but after injection of phosphate the serum value rose and the amount excreted was much greater than in the normal subjects. Glomerular filtration was normal but tubular re-absorption was defective. When vitamin D₂ was given as well to the patients the serum value rose higher than without it, and tubular re-absorption increased by 50 per cent.

Use of a vitamin D preparation which could be given intravenously made possible the conclusion that vitamin D improved the defective tubular re-absorption and delayed the loss of P from the blood.—E. M. Hume.

5238

SALASSA, R. M., POWER, M. H., ULRICH, J. A. and HAYLES, A. B. Observations on the metabolic effects of vitamin D in Fanconi's syndrome.

N.A. and R., October 1954

Proc. Staff Meetings Mayo Clin., 1954, **29**, 214-224.

A daily dose of 400,000 "units" of vitamin D was given for 30 days to 2 patients, aged 16 and 11 years, with Fanconi's syndrome. Carefully controlled metabolism experiments showed that the dose had no immediate effect on the abnormal metabolism, but that it gradually increased the plasma values for bicarbonate and P until they became normal, and reduced the urinary excretion of amino-N and ammonia. Figures are given for the change in excretion of individual amino-acids. There was a significant decrease in the urinary output of sugar in one patient and probably in the other also. The faecal output of P decreased greatly, and the urinary output increased only slightly, so that the P balance improved. Renal clearance of P decreased by 37 and 44 per cent. in the patients. The retention of Ca was increased, though the renal clearance of Ca also increased. Endogenous creatinine clearance was normal before and after treatment. There was associated clinical improvement.—L. Wills.

5239

VAN CREVELD, S. and ARONS, P. **Further experiences in a special case of renal osteoporosis with aminoaciduria, treated with dihydrotachysterol.** *Ann. paediat.*, 1954, **182**, 191-202. [Child. Clin., Univ. Amsterdam.] German and French summaries.

For earlier work see Abst. 5450, Vol. 19.

Further attacks of severe osteoporosis in the patient are reported; they failed to respond to vitamin D and were associated with loss of amino-acids, including cystine, in the urine, but responded to large doses of dihydrotachysterol. The boy, now 6 years old, is kept in good condition on a maintenance dose of dihydrotachysterol; treatment is controlled by estimation of serum Ca.

BADENOCH, J. and FOURMAN, P. **Osteomalacia in steatorrhoea.** *Quart. J. Med.*, 1954, **23**, 165-176. [Nuffield Dept. Clin. Med., Radcliffe Infirmary, Oxford.]

The absorption of calcium and vitamin D was studied in 6 patients with steatorrhoea. Estimation of Ca balance in 2 of them showed that on a high-fat diet without vitamin D the faecal Ca output exceeded the intake, and the balance was still negative after 10,000 I.U. vitamin D daily had been given orally or parenterally. When, however, the Ca intake was increased, and the vitamin was given by intramuscular injection, the balance became positive. Estimation of fat in the faeces showed that when the Ca intake was less than the amount that could combine with the fat present the Ca balance was negative, but it

became positive when the Ca intake exceeded the fat equivalent. When the fat intake was low, daily oral doses of 30,000 I.U. vitamin D and a high Ca intake produced a positive Ca balance. In 3 of the patients, osteomalacia developed while they were receiving 1500 I.U. vitamin D and 2 g. calcium lactate by mouth daily. All the patients recovered slowly when given vitamin D by injection and from 15 to 30 g. calcium lactate daily, but the rate of retention of Ca was very slow.

SCHEPPE, K. J. Studien zur Cöliakie-Rachitis. [Coeliac rickets.] *Monatsschr. Kinderheilk.*, 1954, **102**, 175-176. [Munich.]

A report of a case.

5242

GERTLER, W. Zur Frage der Spätschäden bei der langdauernden Vitamin D-Behandlung der Hauttuberkulose. [The problem of late injury in protracted treatment of skin tuberculosis with vitamin D.] *Ztschr. Tuberk.*, 1953, **103**, 26-50. [Hautklin., Univ. Leipzig.]

Mean values for blood pressure are given for 94 males and 186 females aged from 10 to 80 years, after treatment for skin tuberculosis with 1 mg. vitamin D₂ daily for 2½ and 3½ years in 1948-51. For comparison, mean values are given for patients of the same age without circulatory diseases, attending the Klinik in the same years and not given vitamin D.

After 2½ years treatment with vitamin D there was generally a tendency for the mean systolic blood pressure to be above normal, though the tendency differed at different ages and was more marked in men than women. After 3½ years the mean value was lower than after 2½ years and in women over 40 it was below normal.

Electrocardiograms for 127 patients and tests of kidney function for 172 showed some signs of abnormality not deemed severe. Values for residual N were liable to severe fluctuation, but very few were over 40 mg. per cent., considered the highest limit of normal.

It is concluded that a daily dose of 1 mg. vitamin D₂ can be continued indefinitely without risk of serious injury in patients without clinical contra-indications.

Vitamin D is considered to act by influencing central-nervous regulation of metabolism.

DYGGVE, H. V., DAM, H. and SØNDERGAARD, E. **Comparison of the action of vitamin K₁ with that of synkavit in the newborn.** *Acta paediat.*,

1954, **43**, 27-31. [Dept. Obstet. A, Univ. Hosp., Copenhagen.] French, German and Spanish summaries.

In newborn infants with prothrombin times prolonged to varying extents, there was no significant difference in the rate of action of vitamin K₁ and Synkavit in reducing the prothrombin time when the vitamins were given intravenously in doses of 10 or 0.1 mg., or orally in doses of 10 mg. The results differ from those obtained with vitamin-K-deficient chicks, and with chicks or patients treated with dicoumarol, where it was found that vitamin K₁ acted more rapidly than Synkavit. Administration of *dl*- α -tocopherol given 24 hr. previously had no effect on the action of injected vitamin K₁.—L. Wills.

5244

VERSTEEG, P. and VERSTEEGH, E. T. B. Het gehalte aan proconvertine in het bloed van vroeggeborenen. [**Proconvertin content of the blood of premature infants.**] *Nederland. Tijdschr. Geneesk.*, 1954, **98**, 1296-1298. [Kinderclin., Univ. Amsterdam.] English summary.

Proconvertin, a recently discovered coagulation factor, was estimated in the blood of 39 premature infants of weight between 1500 and 2500 g. All of them had an intramuscular injection of 10 mg. vitamin K on the first day of life, and 10 mg. vitamin K by mouth, some for 2 subsequent days and some to the end of the experiment at 8 weeks of age. There was less proconvertin in the blood of premature than of full-term infants and the upper values were higher in those that continued to get vitamin K, than in those that did not, though the response was less than in full-term infants. One twin with melaena had the same proconvertin value as the normal twin.

DENTAL DISEASES

5250

BRITISH DENTAL ASSOCIATION CHILD DENTAL HEALTH COMMITTEE. **Dental health of children : memorandum.** *Brit. Dent. J.*, 1954, **96**, 199-220.

The Child Dental Health Committee's memorandum (pp. 199-202) covers the line of approach to the problem of dental ill-health and lists the measures likely to be of value for its solution. It recommends acceleration and widening of dental research, fluoridation of water supplies on an experimental scale, fuller use of the dental service for children and extension of education in dental health. Appendix A (pp. 202-219), in 7 parts by a group of authorities whose interest is largely academic, briefly reviews knowledge of the control of caries by local measures, applications of local

N.A. and R., October 1954

measures through oral hygiene, fluoridation of domestic water supplies, causes of malocclusion, diet, breast feeding and dental sepsis. Appendix B (pp. 219-220) summarises the present position of dental health education in the United Kingdom. D. Harvey.

5252

DUNNING, J. M. **The influence of latitude and distance from seacoast on dental disease.** *J. Dent. Res.*, 1953, **32**, 811-829. [Harvard Univ., Boston, Mass.]

This geographical study is based on the results of Britten and Perrott (*Pub. Health Rep.*, Washington, 1941, **56**, 41), Ferguson (*J. Amer. Dent. Assoc.*, 1935, **22**, 392) and Nizel and Bibby (Abst. 759, Vol. 15) for U.S. service recruits, Mills (Abst. 5594, Vol. 7) for U.S. rural schoolboys, Ockerse (Abst. 5461, Vol. 19) for white children in South Africa, Andrews (*Austral. J. Dent.*, 1948, **52**, 12) for men and women of the Royal Australian Air Force, and Saunders (Abst. 2215, Vol. 16) for children in New Zealand.

Analysed by States, the U.S. service data strongly suggested that the prevalence of dental disease (mainly caries) increased from south to north and decreased as the distance from the sea increased; the relationships could be shown to be statistically significant. Mills's data for children corroborated the latitude effect. A similar pattern, inverted, was found in South Africa when districts with over 0.7 p.p.m. F in the water were excluded. Australia showed the latitude effect only. New Zealand did not, possibly because of its small size or the preponderating effects of other local conditions.

Possible reasons for the relationships are discussed in detail. The latitude effect may be related to sunshine or temperature or both. Ockerse's data indicate a significant negative correlation between mean daily sunshine and prevalence of dental disease. As for temperature, it is suggested that in cooler regions there may be a tendency to meet the increased energy requirements with carbohydrate foods. Greater urbanisation in the northern States does not seem to be responsible. The sea-coast effect may be partly due to greater use there of surface water low in F, but there is evidence that total hardness of water, rainfall, and relative humidity may play a part, and further studies on these are required.

W. M. Deans.

5253

PARFITT, G. J. and PARFITT, J. B. **Caries incidence rate—from childhood to middle age.** *Brit. Dent. J.*, 1954, **96**, 183-187. [Dept. Prev. Dent., Inst. Dent. Surg., Gray's Inn Road, London, W.C.1.]

Records from a private dental practice were available for 104 subjects from age 3 years for both temporary and permanent dentitions and for 60 others from age 6 years for permanent dentitions.

From the first set of data the average number of cavities per year in each dentition was calculated; there was evidence that the rates for temporary and permanent teeth were similar. For the second group 16 curves showing the yearly caries experience of individuals are reproduced. Of the 60, 21 showed no change with age, 30 minor deviations and 9 an abrupt change. In only 9 was there a decrease with advancing age.

Possible causes of these differences are considered and in a short appendix the methods of expressing the incidence of dental caries are discussed.—D. Harvey.

5254

GÖBEL, F. and DUFFNER, K. **Vergleichend-Statistische Erhebungen über Zahnerkrankungen bei Mensch und Pferd. [Comparative statistical data on dental diseases in man and horse.]** *Berl. Münch. tierärztl. Wochenschr.*, 1954, **67**, 165-170. [Tierklin., Tierhyg. Inst., Freiburg i. Br.] English summary.

A comparative study over 3½ years of the dental disorders of 4751 human patients in the practice of one of the authors and of 119 horses treated at the *Tierklinik* because they were feeding badly and losing condition showed that, although many disorders are common to man and horse, their incidence differs widely. Caries was by far the commonest in man, but was found in only 3 of the horses. It is suggested, however, that caries is becoming commoner in horses owing to the use of prepared feeds or feeds richer in carbohydrate. On the other hand, 51 horses had lesions due to sharp-pointed teeth, and 29 had periodontitis.

BAŽANT, V., MIKSA, J. and ŠKOPKOVÁ, M. **Zubní kaz a výživa mládeže na Sedlčanskú, Rakovnicku a v Praze v letech 1948 a 1949. [Dental caries and nutrition of the young in the regions of Sedlčany, Rakovnik and Prague in the years 1948 and 1949.]** *Čas. Lék. čes.*, 1954, **93**, 140-144. [1. Stomatol. Clin.] English and Russian summaries.

Surveys were made in the 3 regions of the incidence of dental caries and of the food consumption

of schoolchildren. The items studied were the intakes of calories, fat, carbohydrate and animal and vegetable protein. The composition of the diet was best in the Rakovnik region, worst in Sedlčany and intermediate in Prague. Consumption of rye bread was largest in Rakovnik, and of sugar in Sedlčany. The state of the teeth reflected the composition of the diet, and was best in Rakovnik, worst in Sedlčany and intermediate in Prague. [From summary.]—E. M. Hume.

5256

JONES, R. V. H. and MYNOTT, M. J. **Changes in dental hypoplasia and caries among the children of Finnish Lapps, 1939-50.** *Brit. Med. J.*, 1954, i, 682-684. [St. Thomas's Hosp. Med. Sch., London.]

To find what changes had occurred as a result of disturbed living conditions in their country Finnish Lapp children were examined in 1950 and the data were compared with those obtained by Mellanby in 1939 (Abst. 2049, Vol. 10). Of 92 Inari Lapp children 6 were caries-free compared with 3 of 70 in 1939, and in those between 6 and 9 years of age the percentage of carious teeth was only 42.8 against 68.3 in 1939. The changes in the food supplies of the population during and subsequent to the war time occupation of the country are discussed, and it seems that the lower incidence of caries is due not to greater resistance of the teeth as measured by surface hypoplasia but to external influences, of which the diminished consumption of sugar is probably the most favourable.—D. Harvey.

ONISI, M. and SAITO, H. **Caries susceptibility of the enamel and the cementum in human teeth, with emphasis on the fluorine problem.** *Yokohama Med. Bull.*, 1953, 4, 294-297. [Dept. Microbiol., Dent. Fac., Tokyo Med. Dent. Univ.]

Examinations were made of 3154 teeth extracted by 21 dentists in 17 communities and susceptibility to caries of enamel and cementum was assessed. The possibility is recognised that errors may lie in the assumption that the caries-producing agents attack enamel and cementum equally and independently. From the statistical analysis made it is concluded that the susceptibility of enamel to caries is more variable but less than that of cementum; its being less susceptible may be caused by an action of fluorine.—D. Harvey.

In the children's clinic of the Central Hospital, Salonika, 10 cases of favism, all in boys, were seen in 1952-53, none having been seen previously since 1943. Other hospitals had the same experience. The season was a very wet one. The broad bean (*Vicia faba*) had usually been eaten raw. The

signs and symptoms are described; vomiting and destruction of red cells were prominent. One child of 10 months, still breast fed, became ill after the mother had eaten broad beans without any adverse effect on herself. Case histories are given. The most satisfactory treatment was by blood transfusion; one child for whom this was impossible died.—E. M. Hume.

Vol. 24, No. 4

amino-acids, free and bound, during intravenous administration of protein hydrolysate.] *Nederland. Tijdschr. Geneesk.*, 1954, **98**, 1613-1621. [Kinderclin., Acad. Ziekenhuis, Groningen.] English summary.

Studies were made with a papain hydrolysate of milk protein at the rate of 1 to 2 g. per kg. body-weight in 2.5 or 5.0 per cent. solution. Each solution was tested on a group of 5 children between 3 months and (roughly) 9 years of age to whom it was given intravenously over 24 hr.; and on groups of 5 patients of about 30 kg. weight, to whom it was given over 6 hr. In the 24-hr. test, on the average 5 per cent. of the free α -amino-N given in the 2.5 per cent. solution was excreted; with the 5 per cent. solution, about 8 per cent. was excreted. Of bound α -amino-N given approximately 16 and 24 per cent. was excreted. In the 6-hr. test also more peptide N than free amino-N was excreted. In a patient with rickets given the 24-hr. test before and after treatment, only the excretion of free amino-acid was reduced by treatment. The results of chromatography on resin of the hydrolysate and of the urine of one child of 4 years are shown, and histidine and arginine were estimated in blood and urine before and after a 24-hr. infusion. Chromatography showed that the free acids lost in greatest proportion were threonine, serine and histidine; in bound form losses of tyrosine, phenylalanine, histidine and lysine were relatively greatest. The losses of individual bound acids were not closely related to the amounts in the hydrolysate.

- JACOBI, H. G. (with KAUFMAN, M. and OGATA, T.) **Nutritional studies of juvenile diabetics attending summer camp.** *J. Clin. Nutr.*, 1954, **2**, 22-31. [111 E. 80th St., New York 21.] Spanish summary.

The subjects were 74 boys and 81 girls aged 5 to 17 years. The boys tended to underweight and the girls to overweight; both tended to be tall for their age. At the end of the camp stay 40 per cent. of boys and 37 per cent. of girls had gained weight; 46 per cent. of boys and 45 per cent. of girls had lost weight.

The carbohydrate, protein and fat contents and energy values of the 5 diets prescribed in the camp are tabulated. Average intakes of energy per kg. bodyweight are given for boys and girls of different age groups. About 43 per cent. of boys and 25 per cent. of girls required an increase of food allowance during their stay. Changes in insulin dosage are recorded.

The organisation of these camps has already been described (Abst. 2408, Vol. 24).—F. C. Aitken.

5275

- PLANCHEREL, P. and MOESCHLIN, S. **Über die Verträglichkeit der Fructose bei Diabetes mellitus.** [Tolerance of fructose in diabetics.] *Schweiz. med. Wochenschr.*, 1954, **84**, 28-31. [Med. Klin., Univ. Zürich.] English summary.

Thirty-two patients with stabilised diabetes were given as additional carbohydrate from 16 to 150, but usually 100, g. fructose daily, distributed over the day, for from 4 to 50 days. Before administration of fructose the amount in the urine ranged from 0 to 15, and afterwards from 0 to 205 mg. per cent. In 6 of the patients there was a tendency for the values for total sugar in the blood to rise,

but in 3 of them intercurrent infection was responsible; of the other 3, one was not very well stabilised, in one the rise was temporary, and in the third it was very slight. Fructose disappeared very rapidly from the blood. Glycosuria occurred in 6 patients, of whom 4 were the same as those just mentioned. The insulin requirement was not increased by giving fructose; in 7 the daily dose of insulin could be reduced.

The verdict of von Noorden (*Die Zuckerkrankheit und ihre Behandlung*, Berlin, 1917; 1927), that prolonged consumption of fructose led to deterioration in the diabetic state, could not be confirmed.—E. M. Hume.

5278

- ROSS, C. A. C. and DAWES, E. A. **Resistance of the breast-fed infant to gastro-enteritis.** *Lancet*, **266**, 1954, 994-998. [Dept. Infect. Dis., Univ. Glasgow.]

The 3 strains of *Bacterium coli* used showed negligible growth in synthetic medium at pH below 5 and optimum growth at pH above 7. Tests with one strain showed that at pH 7.1 good growth was obtained in sterile faeces from a breast-fed infant, an infant fed on dried milk and an infant with gastro-enteritis. The pH of faeces from infants with gastro-enteritis ranged from 6 to 9, which is approximately the pH level of healthy artificially-fed infants and is much higher than that of wholly breast-fed infants. Formic acid, which is toxic to *Bact. coli* at low pH, was present in much higher concentrations in the faeces of breast-fed than of artificially-fed infants.

When lactose was given by mouth to 18 babies fed on dried milk the mean pH of the faeces fell from 7.7 to 5.7 in 15.4 days. The lowest levels were maintained for only a few days and pH rose again while the infants were being given lactose.

WOLF, S. A critical appraisal of the dietary management of peptic ulcer and ulcerative colitis. *J. Clin. Nutrit.*, 1954, 2, 1-4. [Dept. Med., Sch. Med., Univ. Oklahoma, Oklahoma City.]

Helping to allay anxiety and tension in the patient is thought to be more fruitful than diet treatment in the management of peptic ulcer and ulcerative colitis.—F. C. Aitken.

5282

MEURLING, S. Postcibal symptoms after partial gastrectomy for peptic ulcer. *Acta Soc. Med. upsalien.*, 1953, 59, Suppl. 3, pp. 127. [Surg. Clin., Royal Academic Hosp., Univ. Upsala.]

Details are given of a clinical study of 624 patients who had undergone partial gastrectomy. Dietetic treatment for those affected, 31.3 per cent., consisted in giving small dry meals with fluids between times, the meals being taken when possible with the patient lying down, and in the exclusion from the diet of foods found by trial to produce discomfort. Milk and milk products were frequently ill tolerated. For immediate post-operative treatment dry and solid food without milk is recommended.—L. Wills.

VAN DE KAMER, J. H., WEIJERS, H. A. and DICKE, W. K. Coeliac disease. 4. An investigation into the injurious constituents of wheat in connection with their action on patients with

coeliac disease. *Acta paediat.*, 1953, 42, 223-231. [Central Inst. Nutrit. Res. T.N.O., Utrecht.] French, German and Spanish summaries.

[This paper appeared in No. 1 of this volume, by title only: Title 1189. It should obviously have been abstracted at that time.]

Gluten from blended Dutch wheat, 4 varieties, was fractionated and the several fractions were tested on a child who reacted in 3 to 6 hr. to very small amounts of gluten with acute abdominal pain, vomiting and slight signs of shock. There was no sensitisation as judged by intracutaneous injection of wheat extract.

Ash, crude fibre and fat of wheat, like wheat starch, produced no reaction and gluten only a slight reaction. Gliadin gave a severe reaction, as did also an aqueous extract of the gluten which contained gliadin, but not an extract with 10 per cent. NaCl which contained no gliadin.

Further tests on 5 children with faecal fat as the indicator confirmed the injurious effect of wheat gliadin. Tests on one child with oatmeal showed that its effect was the same as that of wheat.

I. Leitch.

RAGAZZINI, R., BARTOLOZZI, G. and PRATESI, E. "Il morbo celiaco". Descrizione di due casi. Considerazioni patogenetiche e terapeutiche con particolare riguardo al "fattore frumento". [**Coeliac disease. Account of two cases. Pathology and treatment with special reference to the wheat factor.**] *Riv. Clin. pediat.*, 1953, 52, 223-250. [Clin. Pediat., Univ. Florence.]

A general account is given of coeliac disease, followed by a description of 2 cases with full laboratory findings. One of the patients, a boy of 4 years, was given first the usual treatment and then the dietary treatment of Dicke *et al.* (Absts. 5091, Vol. 23; 5284, Vol. 24) by which all wheat products are withheld. The favourable experience of the Dutch workers was fully confirmed. Measurements of absorption of fatty acids showed the percentage absorbed to be 66 with the first diet and 88 and 92 on two occasions with the wheat-free diet.—E. M. Hume.

SHARP, G. S. and HAZLET, J. W. Evaluation of a new method for supplementation of gastric

hydrochloric acid. *Amer. J. Digest. Dis.*, 1954, **21**, 140-144. [Pasadena Found. Med. Res., Calif.]

A new preparation is described for easy administration of HCl in quantities sufficient to ensure active digestive function. Experience from its use on 104 achlorhydric patients showed that many functional digestive complaints and dietary intolerances could be relieved. The preparation, Normacid (Stuart Co., Pasadena), gradually disintegrates, releasing HCl over a time interval comparable with the physiological secretion by the normal stomach, as was shown by a series by X-ray photographs taken at 15-min. intervals after swallowing the tablet. Each tablet contains betaine hydrochloride 440 mg., methyl cellulose 110 mg. and pepsin (1 to 10,000) 32.4 mg. It is recommended that all patients over 60 years who have digestive complaints referred to the epigastrium should be tested for gastric acidity, and that those with achlorhydria or hypochlorhydria should, if no neoplasm is present, be given this new treatment.—M. B. Richards.

CLEMENTS, F. W. **Endemic goitre in Australia, New Zealand, and Melanesia.** *Bull. World Health Organiz.*, 1954, **10**, 105-111. [Inst. Child Health, Univ. Sydney, N.S.W.] French summary.

New South Wales, South Australia, Tasmania, Victoria and possibly parts of North Queensland are areas where goitre is endemic. In 1947 iodine prophylaxis was introduced. Ten-mg. tablets of

KI were given weekly to pregnant and lactating women and to infants, children and adolescents. Since 1947 the incidence of goitre in Canberra schoolchildren of 9 to 11 years of age has fallen and in 1952 was negligible. In West Australia endemic goitre has not been recorded although other trace-element deficiencies occur there. Practically the whole of Tasmania is an endemic-goitre region, the incidence being greatest in the south of the island.

In New Zealand as a result of iodine prophylaxis started in 1924 large visible goitres have almost disappeared, but the incidence of palpably enlarged goitres is still high. This may be partly explained by the fact that only 80 per cent. of the population use iodised salt, some of which is insufficiently iodised.

In New Guinea the distribution of goitre is irregular. Non-goitre areas are in close proximity to areas where more than half of the men and almost all the women have enlarged thyroids. The crude salt in use in Melanesia can now be iodised and a campaign to educate the people in its use has every chance of success, as salt, one of the chief substances used in barter, is in great demand.—B. W. Simpson.

KOPF, H. **Neure Behandlungsergebnisse kropf-behafteter Neugeborener und Schulkindern in Oberösterreich. [Recent results of treatment for goitre of newborn infants and schoolchildren in Upper Austria.]** *Wien. klin. Wochenschr.*, 1954, **66**, 96-98. [Chirurg. Abt., Krankenhaus Barmherzigen Schwestern, Linz/Donau.]

In Vöcklabruck, treatment of the mother with KI, preferably from the 4th month of pregnancy, reduced the percentage of goitre in the newborn from 47 to about 5, in 2 years. In Rohrbach, notorious for its high incidence of goitre, the attempt has been made for the last few years to give 0.5 mg. KI weekly to every schoolchild, and consumption of iodised salt in the homes has been encouraged. The percentage of schoolchildren with goitre was 66 in 1946, compared with 31 in 1952 after only 2 years' attempted prophylaxis. As further evidence of the beneficial effect of I, the figures are given for Bad Hall, which has drinking water with the highest I content in Austria. The percentage of schoolchildren with goitre is about 11 for those living in Bad Hall but 35 for those nearby and outside; in the region of Steyr, for instance, it is 49. The fact that 11 per cent. of the Bad Hall children have goitre despite the high I intake is taken as evidence that I deficiency is not quite the whole story and that some other condition such as a further dietary deficiency, a toxin or bad hygiene does play some part.—E. M. Hume.

5294

WILSON, D. C. **Goitre in Ceylon and Nigeria.** *Brit. J. Nutrition*, 1954, **8**, 90-99. [Lab. Human Nutrit., Univ. Oxford.]

In the wet areas of Ceylon the percentage incidence of goitre among girls was very high and among boys moderate, but in the dry areas the incidence was generally low for both sexes. The chief condition affecting the incidence of goitre was the high-carbohydrate low-protein diet of the poorer villagers living in the wet areas where the I content of the water was low. Six samples of rural drinking water had low amounts ranging from 1.4 to 2.7 μg . I per litre, and there was much faecal pollution. In Nigeria there was a high percentage of goitre with cretinism and deaf-mutism among families living on the pre-Cambrian granites and using water with a low I content of 0.6 to 0.7 μg . per litre. Those living on basaltic areas were free from goitre and the water in these areas had 5 μg . I per litre. The marine sedimentary regions of the Niger basin were free from goitre.

It is concluded that in the goitre areas of Ceylon and Nigeria lack of I in food and water is of primary etiological importance.—B. W. Simpson.

Over 32,000 children, representing 5 per cent. of the school population and about 2 per cent. of the total population, were examined in all the Department capitals and in some other towns in the 14 other departments of El Salvador.

In the capital, San Salvador, about 8000 children were seen and on the findings it was estimated that out of a total school population of 673,000 children, about 119,000 were suffering from endemic goitre.

The incidence of visibly enlarged thyroids was low, about 6.2 per cent. of the total cases seen. No deaf-mute, idiot or cretin was seen.

The salt used in El Salvador is entirely sea-salt with a mean I content of 0.22 and a maximum of 0.57 parts per 10,000. It is recommended that iodisation of all salt intended for human consumption be started immediately to bring the content up to 1 part per 10,000.

Vol. 24, No. 4

With the possible exception of a general dietetic deficiency of vitamin A, no goitrogenic abnormality of diet was seen.—P. C. Jowsey.

Children with chronic idiopathic anorexia and underweight, ranging in age from 6 months to 10 years, were given 25 mg. aqueous testosterone propionate, intramuscularly, twice weekly for 4 weeks. Increased appetite and weight gain occurred in all.—F. C. Aitken.

ANAEMIA

5299

COLES, B. L. and JAMES, U. **The effect of cobalt and iron salts on the anaemia of prematurity.** *Arch. Dis. Childhood*, 1954, **29**, 85-96. [Dept. Paediat., Elizabeth Garrett Anderson Hosp., Royal Free Hosp. Group, London.]

In all, 126 premature infants were studied, of which 83 were followed for 6 months or longer. The infants were divided at random into 4 groups: group 1 acted as controls; group 2 received 10 mg. cobalt sulphate by mouth daily from the first to the twelfth day of life; group 3 received 20 mg. by mouth daily from 4 to 8 weeks of age; group 4 received 20 mg. with $4\frac{1}{2}$ grains FeSO_4 daily from 4 to 8 weeks. Hb and red cell counts were estimated at intervals from birth. Indications for further treatment were Hb values below 70 per cent., or 75 per cent. at 6 to 7 months, when FeSO_4 was given and red cell counts below 2.5 million, when cobalt sulphate was given.

Administration of Co had little modifying effect on the fall in Hb and red cell count in the first 2 weeks of life. From 2 months of age groups 2 and 3 combined had significantly higher Hb values and red cell counts than groups 1 and 2 combined. Hb values of group 4 remained significantly higher than in any other group after the age of 4 months. None of the group 4 infants required additional treatment. Of the 14 infants requiring additional Fe treatment 8 were controls and groups 2 and 3 had 3 each. All the 4 infants requiring Co treatment were in the control group.

Data are presented showing the incidence of breast feeding and the average weight gains in the groups.—F. C. Aitken.

5301

- LEONARD, B. J. **Hypochromic anaemia in R.A.F. recruits.** *Lancet*, 1954, 266, 899-902. [Royal Air Force Hosp., West Kirby, Cheshire.]

Routine examination of blood of 4221 recruits revealed 50 with hypochromic anaemia but showing no sign; in 2 men there had been haemorrhage from the gastro-intestinal tract and in 1 acholuric jaundice; the remaining 47 cases were classified as idiopathic. Most of the men came from families belonging to social class IV or V of the Registrar-General's classification. In 20 the Hb was under 10.4 g. per 100 ml. blood. The mean corpuscular Hb was low but microcytosis was not prominent. Bone marrow examination showed hyperplastic marrow in 31; in the others it was normal. The degree of hyperplasia corresponded roughly with the degree of anaemia. Test meal examination showed histamine-fast achlorhydria in 43 per cent. of all cases, an incidence similar to that found in middle-aged anaemic women. In 13 patients repeat tests made after treatment showed that free acid had returned in 6. Treatment was with intravenous Fe, 25 mg. saccharated iron oxide for every 1 per cent. that Hb was below normal. The average daily increase in Hb was 0.34 g. at 10 days and 0.19 g. at 4 weeks; the preparation was fully utilised. After treatment the men had a feeling of increased wellbeing, were more energetic and had a greater interest in life.—L. Wills.

5302

- BEUTLER, E., DRENNAN, W. and BLOCK, M. **The bone marrow and liver in iron-deficiency anemia. A histopathologic study of sections with special reference to the stainable iron content.** *J. Lab. Clin. Med.*, 1954, 43, 427-439. [Dept. Med., Univ. Chicago, Ill.]

Detailed studies were made of bone marrow smears and sections from 23 patients with uncomplicated Fe-deficiency anaemia before and after treatment and from 12 normal subjects. The marrow from the Fe-deficient subjects was generally more cellular and contained more erythroblasts than did that of the controls, but in both groups the variability was such that the marrow picture cannot be considered as diagnostic. Though there was no correlation between the degree of anaemia and the degree of erythroblastic hyperplasia in untreated patients, the increase in the degree of hyperplasia found after treatment was roughly related to the initial degree of anaemia. In marrow sections stained for Fe none was detected in material from untreated Fe-deficient patients;

it was present in the marrow of normal subjects. After either prolonged treatment with Fe by mouth, in some cases only after 12 months, or adequate therapy by vein, stainable Fe appeared in the marrow tissue. Sections stained with haematoxylin-eosin-azure showed greenish granules resembling haemosiderin in marrows which by the specific Fe test contained none. Liver biopsies were made on a few patients; before treatment no Fe was demonstrated in the tissue but after Fe by vein it was found, storage taking place apparently in the Kupffer cells. To replenish the body stores of Fe treatment by mouth is necessary long after the blood picture has become normal.—L. Wills.

- MURPHY, W. P. **Pernicious anemia as a problem in geriatrics.** *Geriatrics*, 1954, 9, 99-105. [Dept. Med., Peter Bent Brigham Hosp., Boston, Mass.]

Previous work is reviewed and it is pointed out that in the United States the death rate from pernicious anaemia fell from 5.8 per 100,000 in 1925 to 1.0 in 1948. In a series of 200 living patients 84 per cent. were over 60 years of age and many had survived 19 or more years since diagnosis was made and had led normal, active lives. There was no evidence that the administration of liver had increased the incidence or severity of arteriosclerotic changes, which, as in others of the same age group, were frequently present. The most common causes of death of patients with pernicious anaemia were cardiovascular and malignant disease; the latter affected the stomach in particular, but its development was influenced by the age of the patients rather than by the presence of pernicious anaemia.—L. Wills.

OTHER CONDITIONS

5304

- STAUB, H. **Physio-pathologie et diététique de l'hypertension. [Physiopathology and dietary treatment of hypertension.]** *Schweiz. med. Wochenschr.*, 1954, 84, 1-7. [Clin. Méd., Univ. Basle.]

5305

- TRÉMOLIÈRES, J. and LYON, L. **Les régimes pauvres en sodium dans l'hypertension. Indications. Réalisations pratiques. [Low-sodium diets in hypertension. Indications. Practical results.]** *Diététique et Nutrition*, 1954, 5, 19-31. [Groupe Études Métabol., Sect. Nutrit., Inst. Nat. Hyg., Paris.]

The metabolic effects of diets low in Na and their clinical effects in hypertension are outlined

and the type of diet to be used in different forms of hypertension is discussed. Practical suggestions for rendering the diets palatable are made. Two main diets to provide 1500 and 2300 Cal., respectively, with adjustments to suit different cases, are given, with indications how they may be distributed over the different meals of the day, and a week's menus for the 1500-Cal. diet. Lists of foods to be avoided, to be limited in quantity, or to be given freely, are included.—M. B. Richards.

5306

FINZI, M. Indicazioni pratiche sul "regime di riso, zucchero e frutta" nella terapia dell'ipertensione arteriosa e dell'insufficienza cardiaca. [Practical observations on the "rice, sugar and fruit diet" in the treatment of arterial hypertension and cardiac insufficiency.] *Acta gerontol.*, 1953, 3, No. 5-6, 28-33. [Bologna.]

The rice should preferably be whole, or supplemented with B vitamins and Fe; supplements of vitamin B₁₂ and liver will prevent the complication of anaemia.

Unsalted diet is unappetising and must be faced with patience and resignation, which will be rewarded by physical and psychological improvement.—I. Leitch.

5307

HATCH, F. T. (with ENGLISH, S. A.) Effects of withdrawal and restoration of dietary sodium chloride upon urinary electrolytes in patients with hypertension. *Metabolism*, 1954, 3, 160-167. [Res. Serv., First (Columbia) Div., Goldwater Mem. Hosp., New York.]

The patients studied were, in general, severely ill with hypertensive cardiovascular disease. Serum and urine electrolytes were estimated and body-weight and blood pressure were measured in 11 patients for 1 or 2 weeks during which they received a low-salt diet providing approximately 40 m. equiv. Na, 100 m. equiv. Cl and 80 m. equiv. K daily. The patients were then given the Kempner rice diet which reduced Na and Cl intakes to 4 and 10 m. equiv., respectively, without reduction of K intake, and observations were continued for 5 weeks. Change to the rice diet resulted in marked decreases of urinary excretion of Na and Cl with little change in serum levels. On the average bodyweight declined slightly and blood pressure declined. Estimated decreases in total body Na and Cl during the 5 weeks ranged from 30 to 480 m. equiv. Na and 70 to 620 m. equiv. Cl.

Four patients who had undergone prolonged restriction of NaCl intake, 3 of them on the rice diet, were given tablet supplements of 8.5 or 17 m. equiv. NaCl daily for several weeks. Part or all of the

Cl supplement rapidly appeared in the urine, but excretion of Na remained low for 4 to 5 weeks.

BICKEL, H., GERRARD, J. and HICKMANS, E. M. **The influence of phenylalanine intake on the chemistry and behaviour of a phenylketonuric child.** *Acta paediat.*, 1954, **43**, 64-77. [Dept. Paediat., Univ. Birmingham.] French, German and Spanish summaries.

Treatment of the child with a diet low in phenylalanine resulted in improvement in mental condi-

tion and a fall in phenylalanine levels in blood and urine. After 11 months 4 g. L-phenylalanine were given daily, whereupon there was an immediate deterioration in mental condition and a rise in phenylalanine levels. Return to phenylalanine restriction resulted in improvement in the child's condition. Administration of 4 g. L-phenylalanine was well tolerated in a normal control child.

The preparation of the diet, the basis of which was a phenylalanine-free casein hydrolysate, is described.—F. C. Aitken.

SONI, B. K., MURDOCK, F. R., HODGSON, A. S., BLOSSER, T. H. and MAHANTA, K. C. **Diurnal variation in the estimates of digestibility of pasture forage using plant chromogens and fecal-nitrogen as indicators.** *J. Animal Sci.*, 1954, **13**, 474-479. [State Coll. Washington.]

Six Holstein heifers and 3 wethers, grazing pasture, were used in this study for a 4- and 3-day collection period, respectively. Total collections of faeces were made from the wethers and samples were taken 3 times during each 24-hr. period. With the heifers grab samples were taken. Diurnal variation in faecal N was small but faecal chromogen varied widely and irregularly. With the formula of Reid *et al.* (Abst. 1622, Vol. 22), in which the chromogen content of the forage is not estimated directly, the coefficients of digestibility were very uniform. The average coefficient and

standard deviation for sheep by the chromogen technique was 70.8 and 2.89, and by the faecal N technique 70.4 and 3.08. The results by both methods showed no diurnal variation in digestibility.—D. M. Walker.

5319

SCHNEIDER, B. H., SONI, B. K. and HAM, W. E. **Digestibility and consumption of pasture forage by grazing sheep.** *J. Animal Sci.*, 1953, **12**, 722-730. [State Coll. Washington.]

Three adult rams, 3 yearlings and 3 lambs were grazed on permanent pasture at the bloom, seed and second cutting stage. Digestibility was not affected by age of the animal, but significant differences were found by the chromogen method between the bloom stage 64.4, the seed stage 57.6 and the second cutting stage 56.2. Dry matter eaten daily was 0.8, 1.7 and 2.2 lb. per 100 lb. bodyweight for the rams, yearlings and lambs, respectively. The results agree with those computed from the N content of the faeces but not with those from the T.D.N. requirement.

RAYMOND, W. F. **Studies in the digestibility of herbage. 3. The use of faecal collection and chemical analysis in pasture studies: (a) ratio and tracer methods.**

RAYMOND, W. F., KEMP, C. D., KEMP, A. W. and HARRIS, C. E. **4. The use of faecal collection and chemical analysis in pasture studies: (b) faecal index methods.** *J. Brit. Grassland Soc.*, 1954, **9**, 61-67; 69-82. [Grassland Res. Inst., Hurley, Berks.]

3. Techniques which use feed:faecal ratios or indigestible tracers to predict herbage intake and digestibility by grazing animals are discussed and criticised. Chromic oxide and plant tracers such

N.A. and R., October 1954

as lignin and chromogen are of value only if the sample of herbage analysed is similar to that grazed in the field. Animals tend to select the better quality of herbage and, therefore, plant tracers will underestimate both digestibility and the intake. Lignin and chromogen are criticised on the basis of their digestibility in some circumstances and the diurnal variation in the excretion pattern limits the value of "grab" samples of faeces. Methods based on faecal composition alone appear to be of most value and these are discussed.

4. Using the cold-storage technique described in a previous paper (Abst. 3834, Vol. 24), 40 feeds were given to groups of sheep in metabolism cages and the faeces were analysed for "macerate crude fibre", nitrogen and chromogen. Regression equations relating the digestibility of dry matter and organic matter to the above variables are given. The accuracy of these equations when applied in practice is limited, owing to the wide range of feeds tested, the individual digestive abilities of the sheep and the small number of animals in any one group. The equations obtained in these experiments relating faecal composition (chromogen and nitrogen) to herbage dry matter digested were not in agreement with those of Reid *et al.* (Abst. 1622, Vol. 22) and Lancaster (Abst. 1427, Vol. 19). It is suggested that chromogen measured at 415 m μ , at the peak of the absorption curve, may be a more reproducible value from station to station than that at 406 m μ now in use, which is on the slope of the absorption curve. Analyses for N should be on wet faeces.—D. M. Walker.

TILLMAN, A. D., CHAPPEL, C. F., SIRNY, R. J. and MACVICAR, R. **The effect of alfalfa ash upon the digestibility of prairie hay by sheep.** *J. Animal Sci.*, 1954, 13, 417-424. [Dept. Animal Husb., Oklahoma Agric. Exp. Stat.]

Results of 2 digestibility trials showed that the apparent digestibility of a prairie hay basal ration for sheep was not increased by the addition of a complete mineral mixture or by the addition of alfalfa ash. In the first trial the hay was given with natural feedingstuffs and in the second the hay was the only natural feedingstuff in a semi-purified diet. The trials, run over a series of 6 consecutive 3-day collection periods, indicated that a 3-day collection period was too short for an accurate measure of apparent digestibility.

FRANCOIS, A. C., LEROY, A. M. and ZELTER, S. Z. **Processus digestifs des ruminants. 2. Influence des antibiotiques sur la digestibilité in vitro du foin de luzerne. [Digestion in the ruminant. 2. Effect of antibiotics on digestibility of alfalfa hay in vitro.]** *Ann. Zootec.*, 1954, 3, 9-16. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

Using the technique previously described (Fouconneau *et al.*, *Ann. Zootec.*, 1953, 2, 275) experiments were made *in vitro* to investigate the effects of antibiotics on the digestibility of alfalfa hay. The antibiotics were aureomycin, the Na, K and procaine salts of penicillin, dihydrostreptomycin, didromycin, streptomycin sulphate, and bacitracin. Apart from aureomycin, the amount of which varied from 9.5 to 76 mg. per kg. dry matter of the hay, all were added at the rate of 76 mg. per kg. dry matter. Only aureomycin at all levels, and streptomycin, decreased the degree of breakdown of the carbohydrates, particularly cellulose, and the formation of volatile fatty acids. Procaine penicillin slightly increased the digestibility. All the other antibiotics investigated were without effect.—T. D. Bell.

BREIREM, K. Kraftfôrblandinger. [Concentrate mixtures.] *Landbrukshøgsk. Inst. Husdyrernæring Fôringsslære*, Repr. No. 133, 1953, pp. 40.

The use of concentrates appears to date from about 1880 for oilcakes and a little later for herring meal. The first commercial mixtures were, possibly, made by a Danish firm on the advice of Professor Goldschmidt, in 1909. For more than 10 years later, commercial mixtures were discouraged. The advantages and risks of purchasing commercial mixtures are briefly discussed. There are now regulations and specifications which help to safeguard the buyer. The requirements in respect of specifications are next discussed and then the pros and cons of complex and simple mixtures, possible additions of vitamins and minerals (which may not always be appropriate or beneficial, as, for instance, the use of too much seaweed as a permissible source of iodine in deficiency areas), hormones and antibiotics. The addition of vitamins is often wasteful; for instance, the loss of vitamin A from cod liver oil in concentrates and of vitamin D in mineral mixtures. Supplements are often better given separately. The firm A/S Martens in Bergen has put on the market a molecular distillate of cod liver oil, in powder form, free from harmful unsaturated fatty acids, which is a useful and relatively stable source of vitamin A. Cod liver oil is not allowed in mixtures for pigs.—I. Leitch.

JUON, P. Über die Eigenschaften des Hahnenfusses als Silofutter. 2. Beitrag zur Kenntnis von *Ranunculus acer* L. mit *R. Steveni* Hartm. [Properties of the buttercup as silage. 2. *Ranunculus acer*, L. with *Ranunculus steveni*, Hartm.] *Schweiz. Arch. Tierheilk.*, 1953, 95, 506–510. French, Italian and English summaries.

Molassed silage was made in a concrete pit silo from a natural meadow of which about half was buttercups in full bloom, probably *Ranunculus acer*, L. and *R. steveni*, Hartm., with *R. repens*. When the pit was opened 9 months later the silage was found to be of good quality, with normal colour, pleasant smell, pH 3.95, 2.2 per cent. lactic acid and no butyric acid. The silage was readily eaten by cows which had previously been on good A.I.V. grass-vetch silage, and there was no ill effect on the health or setback in yield or quality of milk. It was concluded that the toxic substance anemonol is destroyed and that grass mixed with buttercups may safely be used to make silage.

LEROY, A. M. and ZELTER, S.-Z. Recherches sur l'efficacité alimentaire des marcs de pomme fermiers. 1. Étude de la variabilité de composition chimique et de valeur nutritive de marcs de pomme fermiers frais. [The feeding value of cider apple residues. 1. Variation in chemical composition and nutritive value of fresh cider apple residues.] *Ann. Zootec.*, 1954, 3, 17–27. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

The residues studied were from small cider presses on local farms. The installations and techniques on these farms are extremely varied, and this is reflected in the composition of the samples. Twenty-nine samples from 25 farms in 7 departments were analysed. Variety of fruit, method of pressing and district all have profound effect. Average figures for proximate composition, acidity, volatile fatty acids and calculated feeding value are given, but the range for each is great, and the value of the averages is doubtful. Possibly the residues could be a useful feed for livestock, but their high content of cellulose and pectic substances limits their application. Further investigations of their suitability will be made.

BELL, M. C., GALLUP, W. D. and WHITEHAIR, C. K. **Value of urea nitrogen in rations containing different carbohydrate feeds.** *J. Animal Sci.*, 1953, **12**, 787-797. [Dept. Animal Husb., Oklahoma Agric. Exp. Stat.]

Three series of digestibility trials and N balance studies were made with Hereford steers which received a ration of prairie hay and one of the following carbohydrate feeds: ground maize, rolled barley, ground milo, dehydrated shredded sweet potatoes, molasses, and maize and molasses together. The protein content was adjusted to 7 to 8 per cent. with cottonseed meal or soya bean meal. In a second period urea was added to bring the protein equivalent to 10 to 12 per cent.

The addition of urea had little effect on the apparent digestibility of the nutrients other than that of crude protein, which was increased in all rations. N retention was also increased, the results being greater with maize as the carbohydrate feed than with molasses. Biological values of total N with urea present were of the same order with the different cereal grains and sweet potatoes in the ration, but urea N was utilised less efficiently when molasses was the source of carbohydrate.—W. Godden.

NATIONAL RESEARCH COUNCIL, U.S.A., COMMITTEE ON ANIMAL NUTRITION. **Hormonal relationships and applications in the production of meats, milk and eggs.** Publication No. 266, March 1953, pp. iv + 54.

Vol. 24, No. 4

Recommendations, based on a review of the literature, are made for the use of synthetic oestrogens and thyroid-active preparations for poultry fattening, egg production, and cattle, sheep and pig husbandry. Limitations in their use are outlined.

Oestrogens are considered commercially useful for production of all classes of poultry meat in that they improve quality and sometimes rate of gain, though efficiency of feed conversion may be reduced. The effects with turkeys are not as striking as with chickens. Thiouracil alone is limited in its usefulness; it is more successful in combination with thyroprotein or diethylstilboestrol. For the production of eggs of high quality the use of thyroprotein cannot be justified.

Further investigation is needed before thyroprotein or antithyroid drugs can be recommended for fattening pigs or ruminants. In cattle and sheep stilboestrol increases rate of gain and efficiency of feed utilisation, but may produce undesirable side effects. Sex hormones have not been shown to be of any advantage in fattening pigs.

Oestrogens can be used to induce lactation in cattle, but in view of the troublesome nature of the side effects and the commercially unprofitable yields, their use for the present is not recommended. When thyroprotein is used to increase milk yield extra feed above maximum requirements is essential. Since mortality rate in calves is increased by feeding the dams with thyroprotein, it is probably better for the average commercial dairy farmer not to adopt the practice.

PINO, N. and LEONTI, F. **Aspetti zoeconomici dell'introduzione in coltura e della produttività del Sorgo Sudan Grass in Sicilia.** [The introduction and productivity of Sudan grass sorghum in Sicily, from the viewpoint of animal production.] *Riv. Zootec.*, 1954, **27**, 132-136. [Ist. Zootec. Gen., Fac. Med. Vet., Univ. Camerino.]

The supply of fodder for fattening calves in Sicily during the hot dry summer is a problem which could be solved by the introduction of Sudan grass. At present maize is used to some extent. Three trials are reported, and the results were encouraging. In the first maize and Sudan grass were compared. Both crops were irrigated, and 4 cuts of Sudan grass were possible, giving a greater total yield of green fodder per acre over the season. In the other 2 trials irrigated and unirrigated Sudan grass were compared. Only 2 cuts of the latter were possible, and the season's yield was low, but the results were not discouraging, since under the conditions no other fodder

could be grown. A comparison is made between the feeding value of Sudan grass and maize, and the former is superior. The importance and advantages of Sudan grass are discussed.

RIVERA-BRENES, L. **Technical and economic aspects of roughage production in Puerto Rico.** *Puerto Rico Agric. Exp. Stat. Tech. Paper* No. 12, September 1953, pp. 117.

The 3 grasses mainly used in Puerto Rico are Merker (*Pennisetum purpureum*), Guinea (*Panicum maximum*) and Pará (*Panicum purpurascens*). These are described. They are best used as silage, and literature on silage is reviewed.

Trials with silages from the 3 grasses, each cut at 40-, 90- and 120-day intervals and ensiled immediately or after wilting for 3, 6 and 24 hr. in the field, are reported. Losses of total digestible nutrients, protein, ash and carotene during wilting and ensiling are discussed. The effect of cutting intervals and species on the lignin content and the proportion of leaf to stem are described.

The shortest cutting interval was most economical and best from the nutrition aspect. Ensiling did not cause an uneconomic loss of nutrients, and the maximum use of arable land, scarce in Puerto Rico, could be made. The hope is expressed that the experiences reported will be used to advantage by Puerto Rican livestock producers.—T. D. Bell.

NYE, P. H. **A survey of the value to the food-farming areas of the Gold Coast. 2. The granitic soils of the far north.** *Empire J. Exp. Agric.*, 1953, **21**, 262-274.

For part 1 of this series see Abst. 1649, Vol. 24. Studies were made of the effect of 60 or 120 lb. ammonium sulphate and superphosphate per acre on yields of early and late millets (*Pennisetum* spp.), guinea corn (*Sorghum* sp.) and groundnuts.

An application of 120 lb. superphosphate per acre increased the yield of groundnuts by 61 per cent. and that of cereals by about 52 per cent. Cereal yield increased by 29 per cent. with 120 lb. ammonium sulphate per acre. Applications of 60 lb. per acre of each fertiliser gave about two-thirds of the increase in yield obtained with 120 lb.

It is considered that the productivity of this region could be doubled by the proper use of inorganic and organic manures.—P. C. Jowsey.

5346

NYE, P. H. **A survey of the value of fertilizers to the food-farming areas of the Gold Coast. 3. The Voltaian sandstone region and the southern maize areas.** *Empire J. Exp. Agric.*, 1954, **22**, 42-54.

CATTLE

GROWTH AND FATTENING

5351

DAVIS, L. R., AUTREY, K. M., HERLICH, H. and HAWKINS, G. E. (Jr.) **Outdoor individual portable pens compared with conventional housing for raising dairy calves.** *J. Dairy Sci.*, 1954, **37**, 562-570. [Dept. Dairy Husb., Alabama Polytech. Inst., Auburn.]

During each of 2 successive winter periods groups of 8 newborn Jersey and cross Jersey calves were housed in individual stalls inside a barn. Similar groups were housed outside in portable pens. In the first winter the pens were sited on uncontaminated land; during the second winter the site was slightly contaminated by older cattle. During the second year half of the calves on each system of management were inoculated with rumen fluid. All the calves received the same ration.

Calves outdoor made greater weight gains and were less affected by parasitic worms and scours. Indoor calves were subject to respiratory troubles. Inoculation with rumen fluid had no significant effect on growth. The superior growth rate of the outdoor calves was maintained during the summer grazing season.—J. N. Aitken.

5352

KIDWELL, J. F. **Growth relations in range cattle.** *J. Animal Sci.*, 1953, **12**, 895-896. *Proc.* [Univ. Nevada.]

5353

ALEXANDER, G. I. **Rearing dairy calves.** *Austral. Vet. J.*, 1954, **30**, 68-77. [Dept. Agric. Stock, Queensland.]

Calves fed by nipple did not gain more rapidly than those that were bucket-fed. The nipple-fed group took longer to consume their milk than the others, and there was less ear-sucking among them. There was not sufficient scouring in either group to determine whether nipple feeding would reduce this disorder.

Vol. 24, No. 4

Calves were successfully reared on 15 gal. whole milk and weaned at 4 weeks old provided they were encouraged to eat a dry starter meal at an early age.

Skimmed milk and a high-protein starter were successfully used to rear calves to 6 weeks of age, after an initial period of 7 to 10 days on colostrum and whole milk. There was no difference between gruel and dry meal feeding. The use of a proprietary penicillin preparation with whole milk, followed by a high-protein calf starter, showed no advantage.—T. D. Bell.

5354

STEIN, J. F., KNOTT, C. B. and ROSS, E. B. **Use of special processed soybean flour and whey solubles in milk replacement formulas for dairy calves.** *J. Dairy Sci.*, 1954, **37**, 373-379. [Dept. Dairy Husb., Pennsylvania Agric. Exp. Stat., State College.]

The growth rates of calves given different replacement formulae were compared. It was found that soya bean flour could replace dried whey, distiller's dried maize solubles, bloodmeal and up to a maximum of 43 per cent. of the non-fat dry milk solids given in the milk replacements. Giving soya bean flour at the expense of all the non-fat dry milk solids resulted in retarded growth. The addition of 10 per cent. dextrose, or 8 per cent. lactose and 2 per cent. dextrose, to diets high in soya bean flour did not improve growth rates. Calves on replacements containing whey solubles responded better than calves on replacements containing dried whey. Supplementation of the diets with 0.05 and 0.25 per cent. DL-methionine did not improve growth rates.—J. N. Aitken.

5355

STEIN, J. F., KNOTT, C. B. and ROSS, E. B. **Use of a special processed soybean flour in milk replacements for young dairy calves.** *J. Animal Sci.*, 1953, **12**, 932-933. *Proc.* [Pennsylvania Agric. Exp. Stat.]

HOPPER, J. H., GARDNER, K. E. and JOHNSON, B. C. **Butyrated lard in the ad libitum feeding of "filled milk" for veal production.** *J. Dairy Sci.*, 1954, **37**, 431-435. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

The bodyweight gains of 12 calves given a "filled milk" made by mixing emulsified butyrated lard with fluid skimmed milk and reconstituted dried non-fat milk solids were compared with those of 22 calves given a similar "filled milk" made with emulsified lard. Bull calves of the 5 main dairy breeds were used. Half of the calves in each group received 3 mg. aureomycin hydrochloride per lb. milk.

Calves given the butyrated lard made gains equal to those of calves on whole milk (see Title 2391, Vol. 23) and greater than those of calves on lard-filled milk. There was no significant difference between calves given aureomycin and the controls.—J. N. Aitken.

5357

ROLLINS, W. C. and GUILBERT, H. R. **Factors affecting the growth of beef calves during the suckling period.** *J. Animal Sci.*, 1954, **13**, 517-527. [Univ. California, Davis.]

Statistical analysis of growth data for 159 calves showed that calves from dams in the age range 7 to 10 years were heavier at weaning and grew faster to 4 months of age than calves from younger cows. Calves from heifers and second calves had a higher growth rate from 4 to 8 months. This was thought to be due to the greater persistency of lactation in younger cows. It was concluded that the lactating ability of the beef cow had a direct effect on the growth rate of the calf throughout the entire suckling period.

In a selection experiment on 25 cows it was found that the future productivity of the beef cow could be estimated from the growth rate to 4 months of age of the first calf.—J. N. Aitken.

5358

BARTLEY, E. E., ATKESON, F. W., FRYER, H. C. and FOUNTAINE, F. C. **Antibiotics in dairy cattle nutrition. 3. Effects of different levels of aureomycin intake upon the growth and well-being of dairy calves, and the association of differences with changes in environment.** *J. Dairy Sci.*, 1954, **37**, 259-268. [Dept. Dairy Husb., Kansas Agric. Exp. Stat., Manhattan.]

For previous parts see Absts. 5185, 5217, Vol. 13.

Male and female Holstein and Jersey calves were divided at random into 3 groups of 10 animals each. One group was given a basal ration, the other 2 groups received in addition aureomycin,

15 or 45 mg. per 100 lb. bodyweight, from 4 days to 25 weeks of age. All the calves were housed in a barn which had not previously been used for calf rearing. The results were compared with those of a previous experiment in which the calves were given aureomycin at the 15 mg. rate and reared in a barn which had proved unsuitable for calf rearing.

The bodyweight gains of the control calves in the new quarters equalled the gains of the aureomycin-fed calves in the old quarters. The aureomycin-fed calves in the new quarters made significantly greater gains than the controls under the same conditions. Among Jersey calves the 45 mg. level was more effective than the 15 mg. level. The reverse was true of the Holstein calves. Aureomycin-fed calves consumed more hay and utilised their feed more efficiently than the controls. The differences were not statistically significant.

MCCALL, R. and GRAHAM, W. R. (Jr.) **The value of several ammoniated products as feed for beef cattle.** *J. Animal Sci.*, 1953, **12**, 798-805. [Quaker Oats Co.]

A product composed of hydrolysed and ammoniated maize cobs and oat hulls effectively replaced up to 40 per cent. of the protein supplement in a fattening ration for steers. Ammoniated molasses replacing 20 per cent. of the protein supplement was also effective. A combination of these 2 products replacing 40 per cent. of the protein supplement produced higher liveweight gains. Substitution of urea for up to 25 per cent. of the protein supplement reduced the efficiency of feed conversion.—J. N. Aitken.

5363

- BOHMAN, V. R., TRIMBERGER, G. W., LOOSLI, J. K. and TURK, K. L. **The utilization of molasses and urea in the rations of growing dairy cattle.** *J. Dairy Sci.*, 1954, **37**, 284-293. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

The following rations were compared in trials on 80 dairy heifers: molasses and urea; maize and soya bean oilmeal; molasses and soya bean oilmeal; molasses, maize and urea. All the animals received hay of poor quality in amounts greater than they would consume. Digestion and balance studies were made on 8 Holstein bull calves.

Animals given soya bean oilmeal with maize or molasses made significantly greater gains than those given molasses and urea or molasses, maize and urea. When hay of good quality replaced the poor hay in the molasses-urea ration adequate gains were made. An increase in daily weight gain was obtained when maize was given with urea and molasses. The digestibility studies showed that molasses depressed the digestibility of dry matter, organic matter, ether extract and crude fibre.—J. N. Aitken.

- JARL, F. Uppfödningsförsök med nötkreatur. 2. [Experiments in rearing dairy cattle. 2.] 1. Olika fet mjölk till S. R. B.-kalvar. [1. Effect of feeding S. R. B. calves on milk of differing fat content.] 2. Syrad skummjolk till laglandskalvar. [2. Effect of feeding Holstein calves on acidified skimmed milk.] *Kgl. Lantbrukshögsk. Statens Husdjursförsök Medd.* No. 51, 1954, pp. 55. English summary. 1. In each experiment there were 3 or 4 groups, representing different levels of fat in milk, each of

8 calves comparable in respect of birthweight, breeding, and age and weight of mother. The milk used was the mixed whole milk of the herd, diluted as required with skimmed milk returned from the creamery. As soon as the calves could eat solid food, they were given hay and concentrates and the amounts eaten were recorded. Up to 7 months, the concentrate mixture was oatmeal 60, wheat bran 10, linseed cake meal 28 and dicalcium phosphate 2 per cent. Although the milk experiment ran only from 5 to 65 days of age in the first 4 experiments and from 5 to 41 days in the fifth, records continued to 1 year of age. Calves were not allowed to graze until they were 4 months old.

The amount of milk given being such as to hold metabolisable energy from milk constant, reduction of the fat content of milk to 2 per cent., vitamins A and D being supplied by cod liver oil at the lowest fat levels, had no evident effect on growth as measured by weight, height at withers and 2 measures of girth, or on health. In the first 4 experiments with relatively high milk allowances, there was no relation of amount of hay or of concentrates eaten to the fat content of milk, but in the fifth, with less milk, consumption of total solid food increased; but within the experiment that of hay fell and of concentrates rose as the fat content of the milk fell from 4 to 2 per cent. At the end of a year there was no significant difference between the calves; what difference in size existed was referable to the sires used.

The experiment in which milk with only 1.5 per cent. fat was tested had to be stopped because that group was in bad condition. The reason was not certain and the test was not repeated.

2. Skimmed milk acidified with 0.1 per cent. acetic acid may be used instead of fresh skimmed milk and is to be preferred in hot weather.

Tables are provided showing quantities of milk of fat content 4.4 to 3.0 per cent. and of skimmed milk to be mixed to give a standard mixture with 2½ per cent. fat, and the amounts recommended from 5 to 180 days of age.—I. Leitch.

- BURRIS, M. J., BOGART, R. and OLIVER, A. W. **Alteration of daily gain, feed efficiency and carcass characteristics in beef cattle with male hormones.** *J. Animal Sci.*, 1953, **12**, 740-746. A group of 3 female and 3 male calves were given weekly intramuscular injections of 1 mg.

testosterone per kg. bodyweight. A similar group received injections of methyl androstenediol at the same rate. Six of each sex received no treatment and served as controls. The rations were good quality alfalfa hay and a concentrate mixture. All animals were slaughtered at 800 lb. liveweight. Weights of wholesale cuts, rate of gain, and feed consumption were recorded.

Calves of both sexes treated with testosterone made significantly greater daily liveweight gains and utilised their feed more efficiently than the controls. Treatment with methyl androstenediol had no effect on daily gain or feed required per unit gain. Calves treated with testosterone had a lower percentage of loin and a higher percentage of round than the controls. Treated females had a higher percentage of chuck than control females. Methyl androstenediol had no effect on carcass characteristics.—J. N. Aitken.

5371

DURHAM, R. M. and KNOX, J. H. **Correlations between grades and gains of Hereford cattle at different stages of growth and between grades at different times.** *J. Animal Sci.*, 1953, **12**, 771-774. [Dept. Animal Husb., New Mexico Agric. Exp. Stat.]

Statistical analysis of data from 424 steers graded at weaning and again as yearlings and at slaughter and from 59 cattle fed as post-weaning calves showed that there was no correlation between grade at weaning and carcass grade. There was a low but significant correlation between yearling grade and carcass grade. Bodyweight gains made during a particular period were associated with grades at the end of that period.

5372

PILLINGER, D. B. and KELLY, J. T. **Beef cattle investigations at Ross.** *Tasmanian J. Agric.*, 1954, **25**, 5-16.

The investigations were made on a farm of 24,000 acres, supporting 11,000 sheep and 400 head of Shorthorn cattle. The farm, the management of the stock and the weather during the investigation are described. The cattle were kept on pasture with supplementary hay, and some silage and turnips during the winter and green forage when pasture was poor. Thirty representative steers were weighed monthly from weaning at 7 months old, when they weighed on

the average 534 lb., till they were slaughtered 12 months later at an average liveweight of 1042 lb. The average daily gain was 1.4 lb., but this varied greatly (0.7 to 2.6) and was closely related to the state of the grazing and the amount of green fodder available. The heavier animals at weaning maintained their advantage, indicating the importance of keeping the calves growing well up to weaning. The average dressing percentage was 57, and carcasses were considered good.

5373

MEYER, J. H., LOFGREEN, G. P. and HART, F. K. **The value of certain supplements for beef cattle fed harvested green alfalfa.** *J. Animal Sci.*, 1953, **12**, 806-811. [Dept. Animal Husb., Univ. California, Davis.]

Crossbred Brahman steers and heifers, 266 animals in all, were used. It was found that green alfalfa cut in the pre-bloom to full-bloom stage and supplemented with a minimum amount of Sudan hay produced 193 and 103 lb. beef per acre during 2 consecutive 30-day periods. Cattle given green alfalfa with free access to Sudan hay produced less beef per acre. Green alfalfa plus 1 lb. barley per 100 lb. bodyweight increased the daily rate of gain. Spraying alfalfa with molasses increased consumption, but daily gain and efficiency of feed conversion decreased.

Methods of calculating total digestible nutrients from requirements for maintenance and body gain and from digestion trial data are compared.

5374

CLARK, R. and BARRIE, N. **Winter feeding experiments.** *Farming in S. Africa*, 1954, **29**, 135-138. [Div. Vet. Serv., Onderstepoort.]

Afrikaner bullocks, 3 years old, were successfully wintered on good quality veld hay. When supplements of urea and molasses, cowpea hay or silage were given alone or in combination the animals gained from 11 to 148 lb. during the winter. In these tests the molasses and urea were incorporated into a meal of maize cobs. Four lb. of the supplements, supplying 0.6 lb. crude protein, were given. Mola-meal, molasses absorbed into cane fibre, could be used instead of maize cobs.

Another method of giving the urea was to dissolve 10 lb. in 80 lb. molasses with a little water, and feed the mixture in troughs. Young cattle kept on poor quality grass hay during the winter and given 1 lb. of this mixture gained weight while controls lost.

To fatten cattle during the winter was not considered economic, since those which only maintained weight caught up during the subsequent summer with those which had gained during the

N.A. and R., October 1954

winter. Cattle which were allowed to lose during the winter, however, never caught up, and in addition carcass quality was adversely affected, so that expenditure on supplements to maintain weight was justified.

Sheep getting hay only for their winter feed lost weight, and the quality of the wool was impaired. Supplements of urea and molasses with or without silage reduced loss of weight and almost prevented the decline in wool quality. Cowpea hay supplement also reduced weight losses, but observations on wool quality have not yet been made.

PAWSON, H. C. and BRUCE, R. **Wintering store cattle. Cockle Park trial, 1952-53.** *Agriculture, J. Minist. Agric. Engl.*, 1954, **61**, 134-138. [King's Coll., Newcastle upon Tyne.]

From December 1952 to April 1953, a group of 10 bullocks inwintered on hay, roots, oats and beans made better gains, average 154 lb., than a similar group outwintered on the same ration without roots, average 94 lb. At the end of the winter, however, the latter were valued at £3 per head more than those inwintered. During the following summer the outwintered group gained more, 165 lb., than the inwintered, 137 lb.

A group of heifers inwintered on the same ration of hay, roots, oats and beans gained more, 151 lb., than another inwintered group on grass silage to appetite, 97 lb.—J. S. Thomson.

5376

JARL, F., NORDFELDT, S., HELLEDAY, T. and MÅNSSON, N. C. Uppfödningsförsök med kött djur. [Feeding experiments with beef cattle.] *Kgl. Lantbrukshögsk. Statens Husdjursförsök Särtryck* No. 99, 1953, pp. 15.

In Sweden there is a tendency to shift from dairy farming, since there is a surplus of milk, to beef production or crop farming without livestock. Co-operative experiments in beef production showed that in rate and economy of liveweight gain to about 21 months of age and 425 kg. liveweight Holstein and Aberdeen-Angus × Holstein calves were superior to SRB, purebred Aberdeen-Angus and crosses between these breeds. The economic inferiority of the Aberdeen-Angus was the result of allowing the calves to suckle and including the cow's feed in the cost of production.

Killing-out percentage varied little. Aberdeen-Angus, purebred and crosses, had more fat in the carcass but did not command a higher price.

Bullocks grew and fattened more rapidly than heifers. Those wintered in an insulated barn did better during the winter than those provided with open shelter, but the difference disappeared in the next pasture season.—I. Leitch.

HARRIS, W. A. and COTTON, R. H. **A study in varying cottonseed cake levels in a beet-belt steer-fattening ration.** *J. Animal Sci.*, 1954, **13**, 483-489. [Holly Sugar Corp., Colorado Springs.]

Cottonseed cake, 1.5, 1.0, 0.5 lb., was used to supplement a typical beet-belt ration of ground maize 6, molasses 3, alfalfa hay 4.5 to 5 and pressed beet pulp or wet beet pulp 60 lb. With the lower levels of cottonseed cake, compensating increments were made in the amount of maize in ration. Comparable groups of 10 to 20 yearling Hereford steers were used. Rations containing higher amounts of cottonseed cake and correspondingly more protein did not improve dressing percentage, grade, or market value and resulted in slower and more expensive gains. When no cottonseed cake was given market value and dressing percentage were reduced. The best results were obtained with 0.5 lb. cottonseed cake.

YAO, T. S., DAWSON, W. M. and COOK, A. C. **Relationships between meat production characters and body measurements in beef and milking Shorthorn steers.** *J. Animal Sci.*, 1953, **12**, 775-786. [U.S. Dept. Agric.]

Correlation coefficients between age, growth and beef characters and body measurements were calculated from data for 101 Beef Shorthorn and 62 Dairy Shorthorn steers. High birthweight was associated with shorter times to reach weaning and final weights, but tended to produce poorer slaughter and carcass grades and dressing percentage. There was a high positive correlation between average daily gain and efficiency of feed utilisation. Slaughter grade, carcass grade and dressing percentage were correlated with one another and these in turn were positively correlated with width and circumference measurements. Height measurements were correlated with one another, as were length measurements; both were negatively correlated with beef characters.

Birthweight had positive correlations with height and length measurements but negative correlations with width measurements. Formulae for calculating indices for beef characters are given.

McCORMICK, J. A. and KIDWELL, J. F. **Producing beef from Holstein steers.** *Nevada Agric. Exp. Stat. Circular* No. 3, October 1953, pp. 15.

Nineteen Holstein steer calves were reared on a calf-feeding system to 23 weeks of age, when they weighed about 400 lb. They were then given hay and pasture only, until they were slaughtered at 2 years old, and about 1200 lb. Over the whole

fattening period average daily gain was 1.83 lb., and hay consumed per lb. liveweight increase was 11.3 lb. The management, which fitted into the normal dairy farm practice with little extra cost of labour or equipment, is described. At slaughter the carcasses graded well. The heavier carcasses were better than the lighter in dressing percentage and composition.—T. D. Bell.

DONKER, J. D., KOSHI, J. H. and PETERSEN, W. E. **The influence of oxytocin-induced udder evacuation on milk and butterfat production in a complete lactation.** *J. Dairy Sci.*, 1954, **37**, 299-305. [Div. Dairy Husb., Univ. Minnesota, St. Paul.]

A set of identical twin cows was used. In the second lactation 1 member was used as a control while oxytocin was injected into the other in amounts ranging from 30 to 1.5 I.U. after each regular milking. During the first 10 weeks of the third lactation the twins were reversed as control and experimental animals. Residual milk was collected after each injection.

Administration of oxytocin resulted in increased yields of milk and butterfat.—J. N. Aitken.

POIJÄRVI, I. Beiträge zur Wirkung der Dauer der Melkpause auf die Intensität der Milchsekretion des Kuheuters. [Effect of the length of interval between milkings on the intensity of milk secretion in the cow's udder.] *Maataloust. Aikakausk.*, 1954, **26**, 50-59. [Landwirt. Versuchsanst., Tikkurila.] Finnish summary.

In 2 experiments with 12 cows in groups of 6, made at 2 periods in lactation, the night milking interval of 12 hr. was extended by 5 or 8 min. daily to 13, 14 or 15 hr. and then gradually reduced to 12 or 13 hr. During 20 days at each time interval the milk yield a.m. and p.m. was recorded. These gradual changes in the length of the interval between milkings had no effect on the average total daily yield for any one group at a given stage in lactation. The average milk yield at the evening milking expressed as a percentage of the 24-hr. yield agreed with that calculated on the basis of the interval between morning and evening milking on the assumption that milk secretion was uniform during the 24-hr. period.—W. Godden.

5390

LOGAN, V. S. **The effect on milk production of legume silage harvested in the bud stage vs.**

N.A. and R., October 1954

full bloom stage of maturity of alfalfa. *J. Dairy Sci.*, 1954, **37**, 247-251. [Animal Husb. Div., Central Exp. Farm, Ottawa.]

The fat-corrected milk yield of cows fed on silage made from alfalfa at the bud stage was significantly higher than that of cows fed on alfalfa silage cut at the full-bloom stage.

Varying the amounts of digestible protein in the meal supplements given with each type of silage had little effect on milk yield. Total digestible nutrient intake and fat-corrected milk yield were closely correlated.—J. N. Aitken.

5391

WARREN, F. S., JOHNSON, R. E., DEMBICZAK, C. M., EATON, H. D., BEALL, G. and MOORE, L. A. Lactation response to artificially-dehydrated and pelleted alfalfa added to a ration of timothy-grass mixed hay and grain. *J. Dairy Sci.*, 1954, **37**, 523-530. [Dept. Animal Indust., Storrs Agric. Exp. Stat., Conn.]

Holstein and Guernsey cows were divided into 6 balanced groups of 4 animals each. All animals were given a basal ration consisting of timothy hay to appetite and grain. Treatment consisted in supplementing the basal ration with levels of 0.5, 1.0 and 1.5 lb. artificially dehydrated and pelleted alfalfa per 100 lb. liveweight daily. The animals within each group were assigned to control and the 3 treatments.

At all levels of supplementation the amount of timothy hay eaten decreased and of grain, dry matter, total digestible nutrients and net energy increased. Average daily milk and fat-corrected milk production increased when alfalfa was given. The greatest response was obtained with the highest levels.

The carotenoid concentration of the milk increased almost directly with each added level of the pelleted alfalfa. Liveweight also increased. The efficiency of feed utilisation, in terms of lb. total digestible nutrients and lb. net energy required to produce 1 lb. fat-corrected milk, was reduced. The vitamin A concentration of the milk did not increase with the level of alfalfa as rapidly in Holsteins as it did in Guernseys.

J. N. Aitken.

5392

BAILEY, G. L., BROSTER, W. H., BROWN, B. B. and FOOT, A. S. The relative feeding value for milk production of two National Cattle Foods. *J. Dairy Res.*, 1954, **21**, 1-4. [Nat. Inst. Res. Dairying, Univ. Reading.]

The economic use of artificially dried forage crops in cattle rations is hindered by variations in their feeding value. The difficulty for the farmer may be overcome if they are previously compounded with cereals into cattle cubes of standard

feeding value. An experiment is described which compared the values of milk production of such cubes (National Cattle Food No. 6) with cubes deriving most of their protein content from imported oilseed residues (National Cattle Food No. 1).

Tests were made in mixed herds of cows with their first calves, with daily yield of from 2 to 4 gal., in 1951-52 and 1952-53. Diets containing hay, N.C.F. 1, and N.C.F. 6, in varying proportions, were allocated at random to the individual cows. The results were evaluated in each year by analysing the relation between milk yield and diet, liveweight being also taken into account. The cattle foods were found to have closely similar values, the slight difference in favour of N.C.F. 1 not being significant.

Practical advantages for the design of the experiment, particularly for dealing with very heterogeneous experimental material, are claimed.

I. McDonald.

5393

HUFFMAN, C. F., DEXTER, S. T. and DUNCAN, C. W. The feeding value of pea and oat silage for dairy cows. *Quart. Bull. Michigan Agric. Exp. Stat.*, 1954, **36**, 298-304.

Oat and pea silage had the following percentage composition (as percentage dry matter in brackets): dry matter 29.0, protein 4.54 (15.7), ether extract 1.23 (4.24), crude fibre 8.3 (28.5), N-free extract 12.2 (42.1); total digestible nutrients were 58.4 per cent. of dry matter and there were 42.8 (147) p.p.m. carotene. The pH was 4. Digestibility coefficients were: dry matter 62.5, protein 68.2, ether extract 58.3, crude fibre 64.0 and N-free extract 63.2.

In 18 reversal trials this silage was used to replace concentrates or hay in the ration of dairy cows. In 3 trials 36 lb. replaced 6 lb. maize and 3 lb. soya bean meal; in 5, 20 to 25 lb. replaced 6 lb. maize; in one, 41 lb. replaced 14.7 lb. hay; in 3, 75 to 85 lb. replaced all the concentrates and hay, and in 6 all or part of the hay was replaced by silage to appetite, without concentrates. In all the trials the replacements maintained satisfactory milk production.—T. D. Bell.

5394

GRASHUIS, J. and VAN KOETSVELD, E. E. Geënsileerde- versus gedroogde suikerbietenpulp. Een voederproef met melkkoeien. [Ensiled versus dried sugar beet pulp. Feeding test with milk cows.] *Inst. Moderne Veevoeding "De Schothorst"*, Hoogland, pp. 19.

The test was with 16 cows fed on 3 kg. hay, 3 kg. dried grass, 3 kg., (or 2 for heifers,) dried pulp, straw and concentrates according to weight and

milk yield, for a pre-period of 27 days. Then for 42 days half of them continued on the dried pulp and half had the same pulp ensiled, in equivalent amount in terms of dry matter. There was a post-period of about a month. There was no measurable difference in performance between the groups. The butterfat of the silage group had a higher Reichert Meissl number; iodine number was low, by Netherlands standards, in both groups, slightly lower in the silage group.—I. Leitch.

5395

MCCULLOUGH, M. E. **Factors involved in forage quality for dairy cows.** *Georgia Agric. Exp. Stat. Tech. Bull.* No. 3, July 1953, pp. 25.

This is a review article in which the literature relating to the following aspects is critically considered: the rumen and its ability to convert simple nitrogenous compounds and cellulose into usable forms of protein and energy; the relative balance between nutrients and its importance; the attributes which measure the ability of a forage to promote milk production.—W. Godden.

5396

FERRARI, E. Foraggi e mangimi dannosi alla qualità del latte ed alla lavorazione casearia. [**Forages and feedingstuffs harmful to the quality of milk and dairy produce.**] *Riv. Zootec.* 1954, 27, 141–143.

Some feeds which have a bad effect on milk, butter and cheese are discussed. Lupin seeds, soya bean, sesame, groundnut, rape, walnut and sunflower cakes and meals should be used with discretion, and the same applies to beet pulp and beet molasses. Tomato seed meal, fishmeal and silkworm chrysalises should never be given to dairy cows. The effect of different types of silage on the cheesemaking quality of milk is discussed. The type of silage has little or no effect on the quality of the milk destined for direct consumption.

KOOIJMAN, I. P. Enige proeven met magnesiumpraeparaten (bitterzout, kieseriet, dolokalsupra en magnesiumoxyd) als bijvoeder voor runderen. [**Tests with magnesium preparations, Epsom salt, kieserite, calcium magnesium carbonate and magnesium oxide, as supplement for cattle.**] *Maandbl. Landbouw-*

voord., 1952, 9, 429–431. [Labs. Physiol. Dieren, Landbouwhogsk., Wageningen.]

In tests with 2 cows it was established that both would take kieserite (27 per cent. MgO), calcium magnesium carbonate (19 per cent. MgO, 30 per cent. CaO) and MgO in amounts giving the equivalent of 10 mg. Mg daily, in as little as 0.25 kg. meal. Only one would take Epsom salt. *In vitro*, the salts were soluble to the extent of 93 per cent. or more in dilute HCl at pH 2.3. The salts may be made into nuts with meal.

Legally, calcium magnesium carbonate may not be used in mineral mixtures for horses or ruminants, but kieserite is allowed. It is better to add it to mineral mixtures on the farm. The cost of kieserite and calcium magnesium carbonate is 3 per cent., or less, of that of MgO. The double carbonate should be used where rations require addition of Ca.—I. Leitch.

HEERMAN, H. A., GRAHAM, G. W. and BOWER, K. W. **The effect of tannins in Korean lespedeza and other feeds on milk production.** *Missouri*

N.A. and R., October 1954

Agric. Exp. Stat. Res. Bull. No. 532, September 1953, pp. 8.

The average tannin content of Korean lespedeza on a dry matter basis fell from 8.94 per cent. in September to 2.89 per cent. about a month later. The seeds contained about 10 per cent. in October. In comparison, alfalfa hay was found to contain 10 per cent. tannins, silage 22.9, dry beet pulp 15.0 and hedge apple, known to reduce milk yield in cows, 26 per cent.

A ration containing about 12 per cent. tannins to which a further addition of 5 per cent. tannic acid was made had no effect on growth, feed consumption or milk yield of cows and there was no digestive disturbance. Tannic acid is apparently converted to tannates in the mouth and upper part of the digestive tract and these are further broken down to non-astringent gallic and pyrogalllic acid.—J. S. Thomson.

RAGAB, M. T., ASKER, A. A. and GHAZY, M. S. **Effect of season of calving, dry period and calving interval on milk yield and lactation period of Egyptian buffaloes.** *Indian J. Dairy Sci.*, 1954, **7**, 8-18. [Dept. Animal Breeding, Fac. Agric., Univ. Cairo, Giza.]

A statistical analysis of 929 lactations of 345 buffaloes showed that those calving in the autumn and winter had slightly higher milk yields and longer lactations than those calving in spring and summer. Length of dry period decreased with advancing age.

The highest yields were obtained from animals whose dry period did not exceed 60 to 90 days. There was a significant positive correlation between calving interval and milk yield.—J. N. Aitken.

RUF, E. W., HALE, W. H. and BURROUGHS, W. **Observations upon an unidentified factor in feedstuffs stimulatory to cellulose digestion in the rumen and improved liveweight gains in lambs.** *J. Animal Sci.*, 1953, **12**, 731-739. [Iowa Agric. Exp. Stat., Ames.]

Soya bean oilmeal, linseed oil, wheat bran, distiller's dark grains, maize and yeast added singly to rumen fermentation flasks stimulated cellulose digestion. Animal by-products, vitamins and casein hydrolysate plus purine bases had no stimulating effect. Evidence suggested that certain roughages, like grain and certain other concentrate feeds, contain an unidentified substance helpful in cellulose digestion in rumen fermentation. Yeast and manure extract were rich sources of the substance, which was found to be heat-stable and soluble in water and ethanol of low concentration. The material appeared to be organic, not a mineral and not a B complex vitamin or a protein. Feed

consumption and liveweight gains of lambs on a semi-purified diet were increased when the substance was added to the diet in the form of yeast. J. C. Gill.

5409

BIELIŃSKI, K. and CHOMYSZYN, M. **Próba określenia wielkości i wytrwałości laktacji u merynoprokosów.** [Tests to determine the volume and duration of lactation in merino sheep.] *Rocz. Nauk rol. [B]*, 1953, **66**, No. 4, 55-68. [Inst. Zootech.] English and Russian summaries.

The milk yields from lambing of 4 merino ewes, hand milked from lambing, and from weaning after 90 days of 7, were measured. For the first group the average length of lactation was 193 days, and the average total yield was 53.7 kg. milk with 8.4 per cent. fat. The second group gave 44.2 kg. milk of 8.5 per cent. fat during 152 milking days. The higher daily yield and longer lactation of the second group was attributed to

the effect of suckling. Milking had no effect on wool production or quality. It is suggested that merino sheep could be exploited for milk production.

TRETYAKOV, N. N. Rentgenologicheskoe issledovanie skeleta novorozhdennykh yagnat s razlichnym urovnem pitaniya. [**X-ray studies of the skeleton of newborn lambs on different feeding levels.**] *Dokl. Akad. Nauk S.S.S.R.*, 1953, 93, 741-744. [Inst. Morf. Zhivot. Im.A.N. Severtsov., Akad. Nauk SSSR.]

Lambs born of ewes on (1) a normal diet, and (2) a normal diet plus 400 g. concentrates were killed and studied anatomically. X-ray examination showed that single lambs from group 1 ewes were much better developed than twin lambs of the same group, and lambs from group 2 ewes better than lambs from group 1 ewes. Twins from group 2 ewes approximated in their development to single lambs from group 1 ewes.—W. Hughes.

JORDAN, R. M. Thyroprotein for lactating ewes and its effect on lamb weights. *J. Animal Sci.*, 1954, 13, 438-442. [Dept. Animal Husb., S. Dakota Agric. Exp. Stat.]

In 3 trials of 7 to 8 weeks each, thyroprotein was given to lactating ewes at levels of $\frac{1}{2}$, 1 and 2 g. per ewe daily. Treated ewes tended to lose more bodyweight than controls but the daily gain, feed intake and efficiency of feed conversion of their lambs were similar to those of lambs of untreated ewes.—J. C. Gill.

5415

GERRING, J. C. Flushing of ewes in fat lamb production. *N.Z. J. Agric.*, 1954, 88, 25-27. [Dept. Agric., Ruakura Animal Res. Stat.]

In each of 2 successive seasons 150 Romney ewes were flushed for 6 weeks before tupping and 150

were grazed over a similar period so that body-weight was just maintained. A second trial, again over 2 years with 300 ewes, is also described. They were divided into 4 groups of 75 ewes each. One group was flushed for 3 weeks before tupping, one for 2 weeks, and one for 1 week; in the fourth flushing was begun when the rams were turned in. Results showed that, for maximum twinning, flushing should be begun at least 3 weeks before the start of the breeding season, and should continue until 5 weeks after the first ewes were mated. Flushed ewes were not found to breed earlier and were slightly more difficult to get in lamb. A net gain of 20 per cent. in lambs alive at 28 days can be obtained by better management of the ewes without extra cost.—J. C. Gill.

5416

GUNNARSSON, P. Fóðrunartilraunir með síldarmjölsgjöf handa sauðfé. [**Feeding experiments with herring meal for sheep.**] *Rit Landbúnaðardeildar, A-Flokkur*, No. 7, 1953, pp. 40. [Reykjavík.]

Experiments were made at 2 centres in the winter 1946-1947, at one of these again in 1947-1948 and at another centre in each of the winters 1947 to 1951. In the first experiments there were 5 groups each of 2 ewes, one control and the others given 50, 100, 200 or 300 g. herring meal daily. Later there were 2 groups only, with from 20 to 50 ewes in each. The supplements were given from February or March to some time in May and weights were recorded in the following autumn. Quantities of herring meal compared were 100 and 300 g., 75 and 150 g., 100 and 150 g.

The herring meal was given with such hay as was to be had, from cultivated or from uncultivated pasture or a mixture. It was readily eaten, and even in the largest amount did no harm. There were more twins with the higher allowances. On the average the lambs, especially twins and ewe lambs, grew better in the group given more herring meal. The difference in weight between groups of ewes when the experiment ceased in autumn was in favour of the greater supplement or such as could be referred to the incidence of twinning.

The recommendation is to give 30 to 60 g. herring meal daily to ewes in winter, increasing the allowance to 75 to 100 g. in late winter if much fodder is given: if fodder is scarce it is better, though more costly, to give a cereal supplement.—I. Leitch.

ROSS, C. V., GARRIGUS, U. S., HAMILTON, T. S. and EARLEY, E. B. Comparing high-, medium-high-, and low-protein corn for fattening lambs. *J. Animal Sci.*, 1954, 13, 433-437. [Dept. Animal Sci., Coll. Agric., Univ. Illinois.]

N.A. and R., October 1954

Thirty lambs were used in a 70-day trial in which lambs given high- and medium-high-protein maize, 13.2 per cent. and 11.03 per cent. crude protein, respectively, made significantly greater gains and produced significantly more wool than those given low-protein maize, 7.72 per cent. crude protein. All lambs were on equal feed, the level of which was determined by the lambs on low-protein maize. J. C. Gill.

JORDAN, R. M. and WEAKLEY, H. **Cobalt salt in lamb rations.** *S. Dakota Agric. Exp. Stat. Bull.* No. 425, March 1953, pp. 8.

Two trials with 60 and 56 Western feeder lambs are described, in which no consistent difference in liveweight gain or feed efficiency occurred, between 4 groups, full-fed and allowed free choice of salt alone or containing $\frac{1}{2}$, 1 and $1\frac{1}{2}$ oz. cobalt chloride per 100 lb. In 3 further trials, in successive years, at another station, 1 oz. cobalt chloride per 100 lb. salt added to a prairie hay, barley and soya bean oil meal ration led to an increase of 0.05 lb. in average daily gain per lamb. Co added to an alfalfa, barley and soya bean oilmeal ration significantly increased the daily gain in 2 of the trials but had the opposite effect in a third. In the final year both prairie and alfalfa hay contained 0.10 p.p.m. Co, 0.03 p.p.m. over the minimum required. J. C. Gill.

MEYER, J. H., WEIR, W. C. and SMITH, J. D. **The influence of high sodium chloride intakes on gain, efficiency of feed utilization, nitrogen balance and feed digestibility.** *J. Animal Sci.*, 1953, 12, 924-925. *Proc.* [Univ. California.] Experiments with lambs.

Vol. 24, No. 4

5423

MEYER, J. H. and WEIR, W. C. **The tolerance of sheep to high intakes of sodium chloride.** *J. Animal Sci.*, 1954, 13, 443-449. [Dept. Animal Husb., Univ. California, Davis.]

Rations with sodium chloride added at levels of 0.5, 4.8, 9.1 and 13.1 per cent. were given to 4 groups of 10 ewes. No significant difference between the groups was found during the growing and fattening period of 71 days. The weight gains of groups were similar during the 154 days of the breeding and gestation periods but during the first 28 days of lactation the ewes receiving 13.1 per cent. NaCl showed a highly significant loss of weight compared with the other 3 groups. Weight gains of lambs were similar in all groups. Analysis of blood and milk constituents showed only serum chloride and milk chloride increased by high NaCl intakes.—J. C. Gill.

5424

JORDAN, R. M. and BELL, T. D. **Effect of aureomycin on suckling lambs.** *J. Animal Sci.*, 1954, 13, 450-454. [S. Dakota Agric. Exp. Stat., State Coll., College Station.]

In a 42-day trial in which suckling lambs were drenched daily with aureomycin and in 2 of 3 trials in which an aureomycin supplement was given to suckling lambs for 33 to 50 days the daily gains of the treated lambs were slightly higher and the feed consumption per 100 lb. gain slightly lower than in controls. The differences were not significant. In 3 further trials implantation of 80 mg. aureomycin into day-old or week-old lambs had no significant effect on rate of gain. J. C. Gill.

5425

BRIDGES, J. H., MILLER, J. C., KAMMLADE, W. G. (Jr.) and KUNKEL, H. O. **Effects of various levels of aureomycin in fattening lambs.** *J. Animal Sci.*, 1953, 12, 660-665. [Dept. Biochem., Texas Agric. and Mech. Coll. System, College Station.]

In all, 154 fattening lambs were used in 3 trials over periods of 84 to 112 days. The lambs were hand-fed on rations of milo and alfalfa hay, with and without cottonseed meal. Addition of aureomycin to these rations at rates of 1.1 to 15 mg. per lb. feed resulted in relatively small increases in rate of gain. In all trials aureomycin at 2.2 to 5 mg. per lb. feed increased feed efficiency, but not at 1.25 mg. or 15.0 mg. per lb. feed.—J. C. Gill.

- BELL, T. D., SMITH, W. H. and ERHART, A. B. **The effect of stilbestrol upon lamb performance in feedlot.** *J. Animal Sci.*, 1954, **13**, 425-432. [Dept. Animal Husb., Kansas State Coll., Manhattan.]

Feeder lambs, 517 in all, were used in a feeding trial of 112 days. Half the lambs received a subcutaneous implant in the jaw of 15 mg. stilboestrol at the outset and half of these received a second implant after 70 days. There was no significant difference in liveweight gain between the groups receiving one and two implants; both of them made significantly greater gains than untreated lambs. Carcase grades and dressing percentages were slightly lower in treated lambs. Twelve died from prolapse of the rectum or from excessive swelling in the rectal and perineal region; all had received 2 implants. Nearly all implanted lambs had preputial swelling and showed distress during urination. Measurements of the urogenital system showed enlarged accessory reproductive organs in the treated lambs.—J. C. Gill.

5431

- JORDAN, R. M. **Effect of stilbestrol on suckling and fattening lambs.** *J. Animal Sci.*, 1953, **12**, 670-679. [S. Dakota Agric. Exp. Stat.]

Twelve 2- to 2½-month-old lambs, implanted in the jaw with 12 mg. stilboestrol and fed over a 71-day period, made the same average daily gains as untreated lambs. Twenty-five 3½- to 4-month old lambs with similar implants gained 0.437 lb. compared with a gain of 0.409 lb. per lamb daily for the controls. The difference was not significant. In the second trial, especially, the treated lambs showed increased mammary development and temporary retardation of testis growth. Milk could be expelled from all treated ewe lambs and most of the treated ram lambs. In a further trial of 91 days with 54 feeder lambs similar implants

increased rate of gain and feed efficiency significantly. Carcase yield was 47.6 per cent. compared with 48.8 per cent. for controls, and the grade was lower. Shrinkage after slaughter was greater in the treated lambs, but cooking losses were similar to those of the controls. N concentration in the urine was similar in the 2 groups but the treated lambs excreted less urine and their N retention was 30 per cent. greater. In field studies without controls 2000 out of 9000 lambs with 12 mg. stilboestrol implants died from urinary calculi and prolapse. After sale further heavy losses due to prolapse occurred amongst the remainder. A 10 per cent. mortality is reported in 3500 other lambs similarly treated.—J. C. Gill.

5432

- JORDAN, R. M. **Effect of level of stilbestrol on growth and fattening of lambs.** *J. Animal Sci.*, 1953, **12**, 680-683. [S. Dakota Agric. Exp. Stat.]

In the first experiment a group of 25 Western lambs averaging 70 lb. were implanted in the jaw with 6 mg. stilboestrol. They were full-fed for 81 days with a control group. Treated lambs gained 0.48 lb. and controls 0.35 lb. daily, the difference being highly significant. Feed consumption was similar and treated lambs required per 100 lb. gain 72 per cent. of the grain and 75 per cent. of the hay required by the controls. In the second trial groups of 36 lambs were used and a third group implanted with 12 mg. stilboestrol was added. Daily rate of gain was very significantly less in the controls than in the treated groups, which differed little. Treated lambs required 70 per cent. of the grain and 53 per cent. of the hay, per 100 lb. gain, required by the controls. Carcase yields and grades did not differ between treated groups but in both trials were lower than for controls. No undesirable effect of treatment appeared during the trial.—J. C. Gill.

JORDAN, R. M. **Urea for pregnant ewes.** *S. Dakota Agric. Exp. Stat. Bull.* No. 429, May 1953, pp. 8.

Three wintering trials with pregnant ewes are described. Ewes receiving protein supplements containing 5 and 10 per cent. urea did as well as ewes receiving soya bean meal in respect of total gain, fleece weight, lambing and weaning percentage, birthweight and 55-day weight of lambs. The urea had no ill effect and was palatable. Ewes receiving 1 part soya bean to 3 parts alfalfa and urea did better than those receiving urea with soya bean and alfalfa or wheat middlings in equal amounts. This was most marked when urea was given at the 10 per cent. level.—J. C. Gill.

HUTCHINGS, S. S. and STEWART, G. **Increasing forage yields and sheep production on intermountain winter ranges.** *U.S. Dept. Agric. Circular* No. 925, September 1953, pp. 63.

A 13-year study of intermountain winter ranges

Vol. 24, No. 4

in respect of the utilisation of forage species by sheep, the influence of precipitation on herbage production and plant density and the effects of grazing intensity on forage yields and on sheep and wool production, is reported. The ranges are characterised by low precipitation and scant vegetation. Palatability controlled forage utilisation. Relative abundance, stage of maturity and weather conditions affected the kind of forage eaten. Herbage production was directly correlated with the rainfall during the previous 12 months. Each additional inch of precipitation increased herbage by about 46 lb. per acre. Increases in total herbage production over the trial were 54, 46 and 34 per cent. for light, moderate and heavy grazing, respectively. At the moderate grazing level mortality was less and ewes were 4 to 18 lb. heavier and produced 1 lb. more wool and 11 per cent. more lambs than those on the heavily grazed range. Income was \$3.46 per ewe on moderate grazing and \$1.69 per ewe on heavy grazing. The study indicates that it is advantageous to rotate grazing from year to year, to leave the range early to avoid grazing during the late winter, and to provide water for sheep each day.—J. C. Gill.

SLLEN, S. B., PETERS, H. F. and MYHR, P. I. **The relationship of clean fleece weight to body weight in range sheep.** *Canad. J. Agric. Sci.*, 1954, **34**, 198-202. [Div. Animal Husb., Exp. Farms Serv., Canad. Dept. Agric., Ottawa.]

The relation between clean fleece weight and bodyweight was analysed to find out whether bodyweight would be a useful criterion for selecting breeding stock with a view to increased wool production. Over 3000 sheep of 5 breeds were examined. The methods of sampling and of statistical analysis are described. The data show that, in general, these measures are highly correlated. It is concluded that despite this high correlation, bodyweight accounts for so little of the variation in clean fleece weight that other fleece and body characteristics should be investigated in order to develop a selection index.—A. W. Boyne.

CRAMPTON, E. W. and NESS, O. M. **A meal mixture suitable as the entire ration to be self-fed dry to pigs weaned at ten days of age.** *J. Animal Sci.*, 1954, **13**, 357-364. [Fac. Agric., Macdonald Coll., McGill Univ., Que.]

Twenty-four litters of pigs were used in 3 replicates of a $2 \times 2 \times 2$ factorial experiment. The piglets were weaned at 10 days old and from then to the normal weaning age of 8 weeks they were given only dry meal diets fed to appetite. The main comparisons studied were terramycin or penicillin supplements, 26 or 30 per cent. protein in the diet and 3 or 8 per cent. fat in the diet.

The penicillin supplement was better than the terramycin, for it gave 14 per cent. higher feed intakes, 18 per cent. faster growth rates and, to a

less degree, better feed conversion efficiencies. Pigs given 30 per cent. protein in the diet grew 28 per cent. faster, ate 12 per cent. more food, and had a 15 per cent. advantage in feed conversion efficiency over those given 26 per cent. protein. The addition of 5 per cent. maize oil to the ration had no effect on feed intake, but growth rate was improved and feed conversion efficiency increased by 18 per cent. The performance of the pigs during the experiment was equal to that usually attained by sow-nursed pigs of comparable breeding.—I. A. M. Lucas.

5455

BECKER, D. E., ULLREY, D. E. and TERRILL, S. W. **Protein and amino acid intakes for optimum growth rate in the young pig.** *J. Animal Sci.*, 1954, **13**, 346-356. [Univ. Illinois, Urbana.]

During 3 trials in one experiment piglets were fed from 3 or 7 to 28 days of age on liquid milk diets containing from 10.2 to 30.6 per cent. protein from dried skimmed milk. The rate and efficiency of growth rose with protein level up to from 22 to 24 per cent. Higher protein levels were of no additional benefit. Whether the pigs were allowed equal amounts of feed, or fed to appetite, did not affect this conclusion.

During 3 trials in a second experiment pigs were fed from 35 to 63 days of age on diets containing from 10.0 to 25.5 per cent. protein, again from dried

skimmed milk. In 2 trials the feed was given twice daily as a slop with water; in the third dry. Equalised feeding was used. Levels of milk protein above 12 per cent. in the diet gave no increase in rate or efficiency of growth. The performance of the pigs in both experiments was satisfactory.

From the results estimates were made of amino-acid levels in the diet to support maximum growth of pigs from 1 to 9 weeks of age.—I. A. M. Lucas.

SCHILLER, K. Über den Ergänzungswert von Eisweissträgern verschiedener Herkunft in der tierischen Ernährung. [Supplementary values of protein feeds of different origin in animal nutrition.] *Arch. Tierernährung*, 1953, 3, 342-359. [Inst. Tierernährung, Forschungsanst. Landwirtsch., Völkenrode, Brunswick.]

In a series of N balance studies and some feeding experiments, nearly all with rats, the biological values of the protein in 3 German varieties of soya beans, one sample of commercial extracted soya bean meal, 3 varieties of lupin seeds and 2 samples of fishmeal were compared. In nearly all the experiments the total protein in the ration was 12 per cent.

There was no marked difference in the biological values of the protein in the 3 lots of soya beans or the commercial meal, but the true digestibility of the protein in the latter was much higher, owing probably to the presence in the beans of some substance inhibiting trypsin. The 3 varieties of lupin seeds showed differences in both biological value and digestibility of their protein, owing probably to the presence of some inhibiting substance, particularly in the yellow lupin seeds, which gave the lowest values and had the most bitter taste. Trials were made with rats, 37 and 87 days old, but no difference due to age was noticed. Steaming one sample of soya beans caused an increase in the biological value of the protein to well above the value for fishmeal protein. Similar but less marked increases occurred with 2 varieties of lupin seeds. These results were confirmed by weight gains in feeding trials with rats. In N balance studies with both rats and young pigs no complementary effect was found between the proteins of the extracted soya bean meal and those of cod meal. Similarly in rats there was no effect between the proteins of lupin seeds and those of cod meal.

It is customary in Germany in feeding pigs to start with a ration containing about 20 per cent. mixed protein from barley, potatoes, soya bean meal and fishmeal and to reduce this gradually to 12 per cent. by the end of the feeding period. N balance studies with rats at 31 and 46 days of age showed that at both ages such a protein mixture at either the 20 or the 12 per cent. level gave a

higher biological value than that from a ration of starch, soya bean meal and fishmeal. At both ages the mixed protein at the 12 per cent. level had a higher digestibility and biological value than at the 20 per cent. level. This suggests that an economy might be effected in the level of protein for young pigs.—W. Godden.

BEESON, W. M., JACKSON, H. D. and MERTZ, E. T. Quantitative threonine requirement of the weanling pig. *J. Animal Sci.*, 1953, 12, 870-875. [Dept. Animal Husb., Purdue Univ. Agric. Exp. Stat.]

Five groups of 3 weanling pigs each were fed on a ration consisting of 88 per cent. maize, 6 per cent. essential amino-acids, without threonine, and 4 per cent. minerals along with vitamins and cerelose. The basal ration of one group contained 0.2 per cent. L-threonine and to it was added 0.4, 0.6, 0.8 or 1.0 per cent. DL-threonine, which gave L-threonine contents of 0.4, 0.5, 0.6, and 0.7 per cent. The experiment lasted 35 days and the highest liveweight gain and the lowest feed consumption per lb. of liveweight gain were attained when the ration contained 0.4 per cent. L-threonine, equivalent to 3 per cent. of the crude protein.

HALE, R. W. Restriction in the feeding of bacon pigs as a means of securing economy of meal conversion. *Res. Exp. Rec. Minist. Agric. N. Ireland*, 1952, 28-32. [Minist. Agric. N. Ireland.]

In 3 similar trials pigs were fed on meal from about 60 lb. liveweight to slaughter weight of about 200 lb. on high or low planes of nutrition, and on each plane the feed was given twice or

thrice daily. On the high plane the pigs received 4 lb. meal at 90 lb. liveweight, increasing to 7½ lb. at 175 lb. liveweight; the low-plane pigs started with 4 lb. meal at 90 lb. liveweight, but increased only to a maximum of 5½ lb. at 180 lb. liveweight. Rates of liveweight increase and feed consumption were recorded for the first 16 weeks of the trials.

Economy of feed conversion was better and rate of liveweight increase greater in the pigs on the high plane, which were fed almost to appetite, than in those on the low plane. On neither plane was there a difference in performance due to the number of daily feeds. The results confirmed previous findings at the same institute (Hillsborough). No explanation is offered for the difference from the general experience that restricted feeding gives more efficient utilisation of feed.

CRAMPTON, E. W., ASHTON, G. C. and LLOYD, L. E. **The effect of restricting feed intake of market hogs during the finishing period on the quality of the bacon carcass.** *J. Animal Sci.*, 1954, **13**, 321-326. [Fac. Agric., Macdonald Coll., McGill Univ., Que.]

Groups of weanling pigs, 25 to 40 lb. liveweight, were fed during the winter or summer to bacon weight of 200 lb. All were fed to appetite up to 110 lb. liveweight. During this period the meal had 16 per cent. protein and the average consumption was 4½ to 5 lb. daily. From 110 to 200 lb. liveweight the protein was reduced to 13 per cent. Half the pigs continued to be fed to appetite, averaging 8.3 lb. meal daily in the winter-fed group and 7.3 lb. in the summer-fed. The other half were restricted to 6.3 lb. meal daily. At slaughter in the winter-fed group on full feed 58 and on restricted feed 70 per cent. gave grade A carcasses with less fat in proportion to lean. The restricted group gained 0.45 lb. less daily and took 17 days longer to reach bacon weight. In the summer-fed group the difference in daily gain between the full and restricted groups was only 0.24 lb. There were only 34 and 38 per cent. grade A carcasses in the full and restricted groups, respectively. Efficiency of feed conversion was the same on full or restricted feeding, 5 lb. feed per lb. liveweight increase in the winter- and 4.2 lb. in the summer-fed groups.—T. D. Bell.

AXELSSON, J. and ERIKSSON, S. **The optimum crude fiber level in rations of growing pigs.** *J. Animal Sci.*, 1953, **12**, 881-891. [Inst. Animal Nutrit., Royal Agric. Coll., Sweden.]

Four experiments are reported, each with 16 pigs of initial weight about 20 kg. The rations used were well balanced, except for fibre, and the pigs were fed to appetite. In each experiment there was a preliminary period, until the pigs reached 30 kg., on a ration containing 6.6 per cent. fibre. They were then divided into 4 comparable groups of 4 pigs, all receiving the same ration except that varying amounts of wheat straw were substituted for grains to give fibre contents of 4.8, 6.3, 7.8 and 9.3 per cent. Each trial was divided into 3 weight periods, 30 to 50 kg., 50 to 70 kg. and 70 to 100 kg., the amount of digestible protein in the ration decreasing from the preliminary period to period 3. Metabolisable energy of the rations was estimated from digestion trials and decreased with increase in fibre content.

Statistical analysis of the data showed that 6.57 per cent. fibre in the ration was optimum for gain in weight and 7.26 per cent. for efficiency of feed conversion. The economical optimum, taking feed cost into account, was 6.64 per cent. fibre. Over the whole period, on the average 11.03 megacalories were consumed per kg. weight gain. Average dressing percentage of the carcasses varied between 72.7 and 73.5 and was independent of the amount of fibre in the ration. There appeared to be a slight tendency for carcasses to decrease in fatness as the fibre content of the ration increased.

WISE, M. B., BARRICK, E. R., WISE, G. H. and OSBORNE, J. C. **Effects of substituting xylose for glucose in a purified diet for pigs.** *J. Animal Sci.*, 1954, **13**, 365-374. [N. Carolina Agric. Exp. Stat., Raleigh.]

Three groups each containing four 2-week-old pigs were fed on a synthetic diet containing 30 per cent. casein, 37.4 per cent. sugar, 26.6 per cent. lard and 6.0 per cent. minerals. For the first

N.A. and R., October 1954

group the sugar was all glucose, for the second a 50:50 mixture of glucose and xylose and for the third all xylose. After a transition period of 7 days, the test period lasted 38 days, with weekly weighings. Group 1 grew normally but the introduction of xylose into the diet reduced the average weekly gain per pig from 3.48 lb. in group 1 to 1.34 in group 2 and 0.76 in group 3. The average weekly food consumptions were 4.89, 3.54 and 2.94 lb. The voluntary activity of pigs in groups 2 and 3 was reduced and their coats became rough and dry. Pigs in group 1 were normal throughout the test.

In a second experiment with 5 pairs of pigs of similar age the ration was altered by increasing the sugar content to 56 per cent. glucose for one pig and 56 per cent. xylose for the other in each pair. The lard was reduced to 8 per cent. The experiment lasted 5 weeks after a transition period and in the second week the N balance and sugar output in the urine were estimated daily. Feed consumption was the same in both groups, but the average weekly gains were 1.63 lb. with glucose and 0.95 lb. with xylose. The N retentions were 19.54 and 7.38 g. weekly and the sugar recovered in the urine 0.64 and 49.72 per cent. of the intake, respectively. Cataracts formed in the pigs receiving xylose.—W. Godden.

HOPE, K. M., WESTON, V. E. and GARSTONE, P. **Whale by-products for pig feeding.** *J. Agric. W. Austral.*, 1954, **3**, 231-233. [Denmark Res. Stat.]

In a series of experiments it was found that whalemeat and whale solubles could be successfully given to pigs as sole supplement to a ration of crushed wheat. Whalemeat was equivalent to meatmeal but whale solubles were slightly inferior. Whale solubles were less satisfactory than meatmeal as a supplement to dried brewer's grains. After 100 lb. liveweight whale solubles could completely replace meatmeal as protein supplement. Carcase quality in all experiments was good.

SENIOR, B. J. and SHEEHY, E. J. **The effect of fineness of grinding on the feeding value of barley for pigs.** *J. Dept. Agric., Republic of Ireland*, 1952-53, **49**, 93-98. [Dept. Animal Nutrit., University Coll., Dublin.]

Three comparable groups of pigs were fed from a week after weaning to slaughter weight on a mixed meal ration containing barley. The barley for group 1 was fine-ground to pass a 1/16-in. screen, and had the consistency of flour. For group 2 it was ground to pass through a 3/16-in. screen, and for group 3 it was only crushed. The percentage of barley was increased gradually from 20 to 45 lb. liveweight to 60 at 110 lb. liveweight. The meal was given as a thick slop. Apart from the difference in fineness, all groups were treated in exactly the same way. The rate of gain, efficiency of feed conversion and final weight of group 3 were significantly less than those of groups 1 and 2, which were the same. It was concluded that coarse grinding was economically desirable, but the added expense of fine grinding was not justifiable.—T. D. Bell.

BOHMAN, V. R., KIDWELL, J. F. and McCORMICK, J. A. **High levels of alfalfa in the rations of growing-fattening swine.** *J. Animal Sci.*, 1953, **12**, 876-880. [Dept. Animal Husb., Nevada Agric. Exp. Stat.]

Four trials with a total of 102 pigs are recorded on the feeding of ground alfalfa at levels up to 60 per cent. of the ration of barley or wheat, or a mixture of these grains, with a protein supplement to appetite. Good growth and feed utilisation were obtained with up to 30 per cent. alfalfa; larger amounts depressed growth rate. No advantage was found in giving terramycin with a ration containing 20 per cent. alfalfa. Carcase quality in all groups receiving up to 50 per cent. alfalfa was graded medium, with a few choice No. 1.—J. S. Thomson.

CAMERON, C. D. T. **Seaweed meal in the ration for bacon hogs.** *Canad. J. Agric. Sci.*, 1954, **34**, 181-186. [Exp. Farm, Nappan, Nova Scotia.]

From the results of a trial made with 72 pigs it was shown that the inclusion of 2, 4 or 6 per cent. seaweed (*Ascophyllum nodosum*) in a balanced ration did not affect weight gain or carcass quality. The balanced ration was of barley, tankage or fishmeal and minerals, and was given to appetite. The pigs were fed from a weaning weight of 40 lb. to slaughter weight of 200 lb., the percentage protein in the ration being reduced at 100 lb. liveweight. The results also indicated, incidentally, that 9 per cent. fishmeal, reduced to 5 per cent. at 100 lb. liveweight, gave a better growth rate than 16 per cent. tankage, reduced to 8 per cent.

CARPENTER, L. E. and LARSON, N. **Antibiotics and the reproduction of swine.** *J. Animal Sci.*, 1953, **12**, 812-818. [Hormel Inst., Austin, Minn.]

Gilts received a ration with or without 2 g. aureomycin per 100 lb. feed until they reached 180 to 200 lb. liveweight; the aureomycin was then reduced to 1 g. per 100 lb. feed and continued for one or two complete gestation and lactation cycles. The suckling pigs had access to rolled oats with 1.8 g. aureomycin per 100 lb. The aureomycin had no significant effect on reproductive performance.

Sows received aureomycin or penicillin by mouth or injection shortly before parturition, and the concentration of antibiotic was estimated in the blood of the sows and of the piglets within a few hours after birth. Neither antibiotic was detected in the blood of the piglets.

Aureomycin given in the diet at 1 g. per 100 lb. was not consistently detectable in the milk, and even after larger amounts were given in capsules the concentration in the milk was small and variable. No difference was seen in the growth of young pigs until they began to eat solid food, when those whose mothers received antibiotic in the feed had access to this as well as to the creep feed.—D. Duncan.

5484

ELAM, J. F., JACOBS, R. L., FOWLER, J., HALE, F. and COUCH, J. R. **Effect of feeding chloromycetin mycelial meal upon the growth and fecal microflora of swine.** *J. Animal Sci.*, 1953, **12**, 819-823. [Dept. Biochem. Nutrit., Texas Agric. Exp. Stat., College Station.]

Five groups of 8 weanling Duroc pigs received for 13 weeks an all-vegetable basal ration alone or supplemented with 0.96 mg. vitamin B₁₂ per 100 lb., or 0.5 per cent. chloromycetin mycelial meal, or vitamin B₁₂ plus 10.4 per cent. meat scraps, or vitamin B₁₂ plus meat scraps plus the mycelial meal.

Neither vitamin B₁₂ nor chloromycetin mycelial meal increased weight gain or feed efficiency. Meat scraps increased the number of faecal clostridia, but chloromycetin reduced the increase and at the same time increased the yeast count and the chloromycetin-resistant organisms.

D. Duncan.

5485

BURNSIDE, J. E., GRUMMER, R. H., PHILLIPS, P. H. and BOHSTEDT, G. **The effect of intermittent**

N.A. and R., October 1954

administration of aureomycin to growing-fattening swine. *J. Animal Sci.*, 1953, **12**, 828-835. [Dept. Animal Husb., Univ. Wisconsin, Madison.]

Nine groups of 9 pigs received a basal all-vegetable ration. Aureomycin was added at 20 mg. per kg. ration either continuously, or intermittently for 3 or 10 days at a time, or during the early, middle or late parts of the fattening period. The results were complicated by an outbreak of bloody dysentery with high mortality.

Aureomycin controlled the dysentery and significantly reduced the number of deaths; the best effect was obtained when it was given continuously. Losses were least when aureomycin was given early in life, but the final weight gain was the same whether it was given early or late. Pigs which received aureomycin continuously through the whole experiment were heavier than those which had it only part of the time.—D. Duncan.

5486

PERRY, T. W., THRASHER, G. W. and BEESON, W. M. **The effect of bacitracin implants on weaning weights and subsequent feed lot performance of two-day old pigs.** *J. Animal Sci.*, 1953, **12**, 824-827. [Dept. Animal Husb., Purdue Univ., Agric. Exp. Stat., Lafayette, Ind.]

Half the pigs in each of 6 litters had a pellet of 22.5 mg. bacitracin implanted subcutaneously at 2 days of age. After weaning at 6 weeks half these pigs and half the control (no bacitracin) pigs received 7.5 mg. aureomycin hydrochloride per lb. feed and the rest the same diet without aureomycin. All were fed to 200 lb. liveweight.

The bacitracin had no effect on weaning weight or on subsequent performance with or without aureomycin. Aureomycin significantly improved growth and feed efficiency whether bacitracin had been given or not.—D. Duncan.

5487

PIERCE, E. A. **The effects of rations containing antibiotics and trace mineral salt on the chemical composition and physical characteristics of pork carcasses.** *J. Animal Sci.*, 1954, **13**, 338-345. [Dept. Animal Husb., S. Dakota Agric. Exp. Stat., College Station.]

To the basal ration of 4 groups of pigs aureomycin-vitamin B₁₂ or terramycin supplements were added from weaning to 125 lb. liveweight or from weaning to slaughter weight at 200 lb. Another group got a supplement of trace minerals instead of the usual simple common salt mineral mixture. Analyses and appraisal of carcasses showed that there was no difference between the groups, though the supplemented groups tended

to have more fat. Chemical analysis of the fat showed a slightly higher moisture content in the supplemented groups.—T. D. Bell.

5488

ROBINSON, K. L., COEY, W. E. and BURNETT, G. S. **The response of pigs to dietary procaine penicillin.** *Empire J. Exp. Agric.*, 1953, **21**, 275-282.

With the time taken by pigs of 60 to 70 lb. liveweight to eat a limited ration as criterion, it was shown that the addition of 2 mg. procaine penicillin per lb. feed stimulated appetite, whether the ration was all-vegetable or contained white-fish meal. The extra palatability of the latter reduced the time compared with the all-vegetable ration, and in all cases procaine penicillin decreased the time still further. The response was greater on the less palatable diet. With weanling pigs fed from 30 to 100 lb. liveweight to appetite on meal containing white-fish meal the addition of procaine penicillin did not increase feed consumption: the observed increase in rate of liveweight gain was probably due to the increased efficiency of feed conversion. Comparing the same groups of pigs from 100 to 210 lb. liveweight, penicillin being withdrawn at 100 lb. liveweight, the rate of gain of the formerly supplemented groups was less than that of controls. In one group the penicillin was not withdrawn and daily liveweight increase was slightly better than in controls. With pigs fattened from 100 to 210 lb. liveweight which had not previously had any antibiotic, on a meal containing white-fish meal, the response to procaine penicillin was slight as regards rate of gain, but feed efficiency was greater.—T. D. Bell.

- BARBORIAK, J. and SCHÜRCH, A. **Versuche zur Feststellung der Wirkung beschränkter VEL-Mengen in tierischen Futtermitteln. [Effect of limited amounts of VEL in animal feeds.]** *Mitt. Schweiz. Landwirtsch.*, 1953, **1**, 172-175. [Inst. Haustiernährung, Eidg. Tech. Hochschule., Zürich.]

Peasants often give dishwater to pigs on account of the remains of food in it, and the fear has arisen that the presence of the widely used detergent VEL or PEO (Colgate-Palmolive A.G., Zürich) may give rise to digestive troubles. An 8-week feeding experiment was therefore made with groups of 20 male and 20 female rats about 4 weeks old at the outset. No significant effect on growth was found when 0.2, 0.5 or 1.0 per cent. VEL was added dry to the Institute's usual ration for growing rats, or when VEL was dissolved in water and used to moisten the feed. Organs examined at post mortem were normal. Since the 0.2 per cent. level would correspond to the case of a 60 or 70 kg. pig getting 3 kg. dry feed and 10 litres of water containing 6 g. VEL, it was concluded that dishwater containing VEL is unlikely to hurt pigs.—W. M. Deans.

- BRATZLER, L. J. and MARGERUM, E. P. (Jr.) **The relationship between live hog scores and carcass measurements.** *J. Animal Sci.*, 1953, **12**, 856-858. [Dept. Animal Husb., Michigan Agric. Exp. Stat.]

Three experienced judges assessed 434 live pigs for percentage of high value cuts, average backfat thickness and length of carcass. The pigs were then slaughtered and the true measurements were correlated with the estimated scores. Judging was most accurate for backfat thickness and length, especially for pigs in the lighter weight ranges,

and least accurate for the percentage yield of high value cuts. It was concluded that considerable training and experience are necessary to grade accurately live pigs of all weights into grades based on carcass measurements.—I. A. M. Lucas.

- CRAMPTON, E. W., ASHTON, G. C. and LLOYD, L. E. **Improvement of bacon carcass quality by the introduction of fibrous feeds into the hog finishing ration.** *J. Animal Sci.*, 1954, **13**, 327-331. [Fac. Agric., Macdonald Coll., McGill Univ., Que.]

The introduction of fibrous feeds to replace the more digestible parts of a fattening ration increased the percentage of grade A carcasses, owing to an increase in the proportion of lean to fat. The fibrous feeds were alfalfa, wheat bran or wild oats, and they were combined with basal rations of oats, wheat or barley. The improvement was due to decreased rate of daily liveweight gain and longer finishing period when alfalfa or wheat bran replaced half the wheat or barley; when the basal ration was entirely oats, without replacement, the same effect was seen. When 25 per cent. of the basal ration was replaced by wheat bran or wild oats there was also an improvement, although rate of gain was not altered. It is suggested that in this case there must be something inherent in the feed to account for the improvement.

- WARREN, W. M. and DICKERSON, G. E. **Components of performance in selecting for heterosis in swine.** *Missouri Agric. Exp. Stat. Res. Bull.* No. 511, November 1952, pp. 71.

Pigs of 2 inbred Poland China lines were cross-bred with 9 different strains of 5 breeds to give 18 crosses, with reciprocal matings of each. In all, 807 pigs were born, growth studies were made on 521 and carcass measurements on 274. Pigs born in spring were reared on pasture with access to shelled maize and a protein supplement and autumn pigs in dry lot with free or restricted feed intake. Feed recording started at weaning, at 56 days of age, and pigs were slaughtered at 200 lb.

N.A. and R., October 1954

From 2 to 6 spring-born gilts of each cross, 81 in all, were mated and slaughtered 15 to 30 days later for counts of ovulations and of embryos. The statistical methods employed are fully discussed.

Indices for selection are constructed on the prolificacy of crossbred gilts, the rate of gain of progeny, feed consumption per 100 lb. liveweight increase, and carcass merit as indicated by the yield of loin. Iowa Landrace crosses were significantly superior to all others except Beltsville Landrace and outbred Durocs. Limited feeding reduced the mean returns for all crosses, but increased the returns from outbred Duroc crosses, which tended to become too fat on unrestricted feeding.—D. Duncan.

BLUNN, C. T., WARWICK, E. J. and WILEY, J. R.
Interrelationships of swine weights at three ages. *J. Animal Sci.*, 1954, 13, 383-388. [Univ. Nebraska.]

Weights were recorded at birth and at 56 and 154 days of age from 491 purebred and crossbred pigs farrowed by gilts in spring and reared on pasture in Indiana in 1947-49; 606 mixed crossbred pigs farrowed by gilts in autumn at Lincoln, Nebraska, in 1947-50; and 797 inbred Duroc pigs reared by gilts and yearling sows in spring and autumn at North Platte, Nebraska, in 1948-50. Thus both genetic make-up and management differed.

The average birthweights were similar at all 3 places, but Indiana pigs grew faster and were heavier at 56 and 154 days than any Nebraska group except Lincoln 1950 autumn pigs. There were statistically significant positive correlations between weights at birth and 56 days ($r = +0.53$), at birth and 154 days ($r = +0.40$) and at 56 and 154 days ($r = +0.63$), but while the regressions are large enough to indicate the desirability of heavy birthweight the coefficients of determination (r^2) indicate that birthweight is a relatively poor indicator of future weight or gain. Similarly, weight at 56 days accounts for only 40 per cent. of the variance in weight at 154 days, so selection on weight at 56 days is not very efficient. Selection of litters with large numbers of pigs alive at 56 days would accomplish nearly as much in selecting for heavy litter weights at 154 days as would selection on weight at 56 days.—D. Duncan.

BRADFORD, G. E., CHAPMAN, A. B. and GRUMMER, R. H.
Time of farrow and performance in spring farrowed pigs. *J. Animal Sci.*, 1953, 12, 848-855. [Dept. Genetics, Univ. Wisconsin, Madison.]

An analysis is given of litter records from 445

Vol. 24, No. 4

Wisconsin farms for the years 1947 to 1950. The numbers of pigs farrowed, the viability to 154 days of age and the litter weights at 154 days of age were recorded for gilts' litters farrowed during a period ranging from early January to early June of each year. Within this range of dates the period at which the gilts farrowed had little apparent effect upon any of the measures studied. This is important because in Wisconsin the greatest numbers of pigs are farrowed during March and April, which causes a very heavy supply of pigs to the packing stations in the autumn and a consequent fall in prices.—I. A. M. Lucas.

5503

LUCAS, I. A. M.
Some further observations upon pigs reared in cold pens. *J. Agric. Sci.*, 1954, 44, 369-376. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Pigs were reared in a cold environment in pens with concrete floors. Some pens were well drained and the straw bedding was kept dry; other pens were continually damp until the pigs were weaned at 9 weeks, after which dry bedding was provided. The pigs were creep-fed from 8 weeks and were kept in the pens in groups of 4 from weaning to bacon weight. Owing to losses of litters the numbers of pigs were too small for satisfactory analysis of the results. The average relative humidity (R.H.) in the 9 weeks before weaning was about 80 to 85, with a range from 60 to 95 per cent. Air velocity near ground level in the pens varied with the weather from 11 to 30 ft. per min.

Four of the 16 pigs in each group died before weaning; there was only one rather doubtful diagnosis of liver disease, in the wet floor group. All the survivors were weaned in reasonable health, and a rather lower weaning weight in the wet floor group was accounted for by a single small deformed pig. No anaemia occurred.

After the pigs were weaned the air temperature in the piggery rose steadily except for a cold spell 4 to 5 weeks later, and the mean R.H. fell to 75 per cent. Three pigs from the wet floor group were killed at 40 weeks and showed signs of liver disease. It was considered that 2 of them developed the disease at 13 to 15 weeks of age, when a check in growth occurred, and the third at 20 to 22 weeks. There was no significant difference in feed efficiency or carcass quality in the other pigs, though pigs reared on wet floors were shorter and fatter than those from dry pens.—D. Duncan.

PUHAČ, I. and HRGOVIĆ, N.
[A contribution to the study of local climate in piggeries.] *Acta vet., Belgrade*, 1954, 4, 15-27. [Inst. Vet. Hyg.] English summary.

Internal and external temperatures, rate of air-flow, cooling and radiation, and humidity of 16 piggeries in Vojvodina were measured during the 4 months from December to March. The floor space, surface area, cubic space, air supply and heat losses were calculated for a pig of 60 kg.

The information obtained indicated the importance of warmth in piggeries. In good farrowing houses there was a difference of 10° C. between

the internal and external temperatures, and good results were obtained at an internal temperature of 10° C. In houses for other pigs the difference was 6° to 8° C. Floor space, surface area, cubic space and air supply per pig were large. (From summary.)—T. D. Bell.

POULTRY

GROWTH AND FATTENING

5507

HILL, F. W. and DANSKY, L. M. Studies of the energy requirements of chickens. 1. The effect of dietary energy level on growth and feed consumption. *Poultry Sci.*, 1954, 33, 112-119. [Agric. Exp. Stat., Cornell Univ., Ithaca, N.Y.]

Twenty chicks were fed from day-old on a control ration containing 20 per cent. crude protein and made up of soya bean oilmeal 12, crude casein 8, fishmeal 4, dried whey 2.4, minerals 3.5, vitamins, glucose 21, wheat 10 and maize meal to 100. In 11 weeks they had a mean feed consumption of 4363 g. and finished with a mean weight of 1491 g. A second group received a similar ration, but with 40 parts of oat hulls added at the expense of maize and wheat, with adjustments in the levels of soya bean and casein to keep the protein content constant. These ate 5448 g. of their ration per head, and weighed 1456 g. Although the second group ate a greater weight of feed, their calculated intake of productive energy was only 6064 Cal. as compared with 9374 Cal. for the first group. Also, although the liveweight gains were similar, the carcasses of the first group contained 27 per cent. fat, and those of the second group only 16 per cent. The mean weight of the gizzards was 26 g. for the first group and 37 g. for the second. Further groups receiving 10 to 30 per cent. of oat hulls gave results intermediate for all these variables.

Another group received a mixture of 60 parts of control ration and 40 parts of oat hulls. In 11 weeks they ate 5329 g. per head, an amount estimated to contribute 6869 Cal. productive energy :

their mean liveweight was 1371 g. Performance was inferior to that obtained with oat hulls added at the expense of grains and with the protein kept at a constant level.

In a second growth trial oat feed and cellulose were compared as "inert" supplements. At the 20 per cent. level growth and feed consumption were similar with each supplement. At the 40 per cent. level the chicks ate more of the "oat hull" ration; it was considered that the greater bulk of the "cellulose" ration prevented the chicks from increasing their feed intake further to compensate for the low energy content of the ration.—K. J. Carpenter.

5508

PETERSON, D. W., GRAU, C. R. and PEEK, N. F. Growth and food consumption in relation to dietary levels of protein and fibrous bulk. *J. Nutrition*, 1954, 52, 241-257. [Dept. Poultry Husb., Univ. California, Berkeley.]

Chicks were fed from 9 to 29 days of age on a series of rations, each containing 2 per cent. soya bean oil and minerals and vitamins believed to cover their requirements with an ample margin. Boned acetone-extracted fishmeal, of known good quality, and rice hull cellulose were variable components, and each ration was completed with sucrose. With fishmeal contributing 21.3 per cent. protein, and no cellulose, chicks had a growth rate of 6.3 per cent. per day, calculated in terms of their mean bodyweight over the test period; with 12, 24, 36 and 48 per cent. of cellulose growth rates were 6.6, 6.0, 5.3 and 2.3 per cent., respectively. With increasing levels of cellulose, up to

N.A. and R., October 1954

24 per cent., feed consumption increased so that the intake of "metabolisable calories" remained constant. For the rations containing 36 and 48 per cent. cellulose the volume of feed eaten remained the same as for the 24 per cent. ration, and the energy intake was therefore reduced.

Rations of lower protein content were also tested. In the extreme case a ration with 5.3 per cent. protein and no cellulose failed to allow any growth; but the same ration supplemented with 12, 24 and 36 per cent. cellulose allowed increasing growth rates, 2.2 per cent. per day at the last level. Carcase analysis of selected birds showed that those that had received low-protein rations contained less protein but more fat than normal chicks. The addition of 12 and 24 per cent. cellulose reduced the fat content of the carcasses, regardless of the protein content of the rations.

It is concluded that chicks normally adjust their feed intake to provide them with "metabolisable calories" in a quantity related to their body size. There is, however, an upper limit to the bulk that they can take in. Growth will normally be limited by energy intake; but with rations low in protein this will be the limiting factor. The apparent growth stimulation by cellulose with the 5.3 per cent. protein ration is thus explained as being directly due to the greater feed and therefore greater protein intake as the energy content of the ration is reduced.

In a further trial the addition of either 2.0 per cent. calcium gluconate or 0.1 per cent. levulinic acid to the same type of ration had no growth-stimulating effect. Levels of both 15 and 20 per cent. protein were used, and the trial was replicated with and without the addition of 12 per cent. cellulose.—K. J. Carpenter.

5509

KINDER, Q. B. and KEMPSTER, H. L. **Experiments in chick feeding 1947-1952.** *Missouri Agric. Exp. Stat. Res. Bull.* No. 525, July 1953, pp. 24.

In the large series of growth tests described the rations were based on yellow maize meal and soya bean meal, deficient in riboflavin. Riboflavin was added as alfalfa meal, dried milk or crystalline riboflavin and the effect was also tested of addition of meat scrap, fishmeal and iodinated casein.

In battery tests addition of alfalfa meal, though preventing curled toe, tended to depress growth to 8 weeks, each 1 per cent. addition over the 1.5 per cent. level depressing growth by nearly 2 per cent.; 5 per cent. alfalfa supplied all the riboflavin required, since the further addition of crystalline riboflavin gave no extra growth response. Crystalline riboflavin could replace dried milk or alfalfa as a source of riboflavin. Replacement of

part of the soya bean meal by 5 per cent. fishmeal gave a 10 per cent. increase in rate of growth and improved efficiency of feed. The continuous addition of iodinated casein, 18 g. per 100 lb. feed, depressed growth but the effect was less marked if the ration contained fishmeal. The use of wheat by-products instead of whole wheat had an adverse effect on growth and feed use. Dried fermentation solubles was a satisfactory source of riboflavin.

From a series of tests on the value of adding vitamin B₁₂, antibiotics and fishmeal to a maize and soya bean meal ration, singly or in combination, it was concluded that vitamin B₁₂ improved growth rate by about 9 per cent., antibiotics by a further 8 per cent. and fishmeal by a further 5 per cent. Under farm brooding conditions built-up litter improved growth rate to 8 weeks only if the ration was deficient in animal protein and vitamin B₁₂. The use of 15 to 20 per cent. of wheat shorts and bran reduced the energy value of the ration of soya bean meal and maize by 2.6 Therms per 100 lb. and resulted in a 2 to 2½ per cent. decrease in growth rate and use of feed was less efficient by 6 per cent.—J. S. Thomson.

SWART, L. G. and LIEBENBERG, C. R. **Lupins in chick rations.** *Farming in S. Africa*, 1954, **29**, 227-229. [Stellenbosch-Elsenburg Coll. Agric., Stellenbosch.]

Sweet yellow lupin seed meal could be used, up to 15 per cent. of the total ration for chickens, but it is recommended that not more than 10 per cent. should be used, replacing about 37 per cent. of the fishmeal normally used. Higher amounts had a detrimental effect on growth and conversion of feed. Bitter blue lupin seed meal, even at a 10 per cent. level, proved an unsuitable protein supplement.—J. S. Thomson.

5513

WIETLAKE, A. W., HOGAN, A. G., O'DELL, B. L. and KEMPSTER, H. L. **Amino acid deficiencies**

of casein as a source of protein for the chick.

J. Nutrition, 1954, **52**, 311-323. [Dept. Agric. Chem., Coll. Agric., Univ. Missouri, Columbia.]

In a series of trials chicks were fed from hatching to 4 weeks of age on a basal ration made up of casein 35, soya bean oil 10, salts 5, cellulose 3, DL-methionine 0.5, quantities of all the crystalline vitamins known to be needed by chicks, and glucose to 100. If no supplement was given feathering was poor, some chicks developed an abnormal gait and they finished with a mean weight below 150 g.

Performance was much improved when the rations were supplemented with either 1.5 per cent. creatine and 0.5 per cent. L-arginine or with 10 per cent. gelatine at the expense of casein, but was not equal to that obtained with a combined supplement of creatine, arginine and 1.5 per cent. glycine. The variability in final bodyweight (with a mean of over 350 g.) was also considerably less with the last ration than with those supplemented only with gelatine or with only arginine and creatine.

Creatine was not essential to optimum performance, as equally good results were obtained with a supplement of 1.24 per cent. arginine and 1.5 per cent. glycine. There is a suggestion from the results that male chicks require more arginine than females.—K. J. Carpenter.

TARR, H. L. A., BIELY, J. and MARCH, B. E.

The nutritive value of herring meals. 1. The effect of heat.

BISSETT, H. M. and TARR, H. L. A. **2. Effect of heat on availability of essential amino acids.** *Poultry Sci.*, 1954, **33**, 242-250; 250-254. [Pacific Fish. Exp. Stat., Vancouver.]

1. The commercial meals were prepared by cooking, pressing and direct flame drying to give a meal of average quality, while the low-temperature meals were prepared by drying the pressed cake at 37° to 43° C. for 24 hr. in a rapid air stream. Some portions of this latter meal were subsequently heated for 30, 60 and 180 min. at 149° C.

The meals were incorporated at a 12 to 13 per cent. level in rations containing maize and soya bean oilmeal and gave rations of 18 to 20 per cent. protein. These feeds were given to groups of 20 day-old New Hampshire chicks. The commercial meals did not give such a good growth response as the low-temperature meal; heating the latter to 149° C. for 60 min. improved the nutritive value. The basal ration alone gave as good growth as the rations containing the low-temperature meal. In a second experiment, all the experimental rations contained 20 per cent. protein and were supplemented with vitamin B₁, vitamin B₆, inositol, p-aminobenzoic acid, folic acid, menadione and

α-tocopherol. The rations containing the commercial meals allowed about the same growth as the rations containing the low-temperature meal. Again the feeding value of the low-temperature meal was improved by heating to 149° C. except when the extra vitamins were given. In a third experiment, groups of 22 New Hampshire day-old chicks were given a 21 per cent. protein ration containing the herring meals with either the vitamin supplement previously used or 2 g. procaine penicillin G per ton of feed. The addition of either the vitamin supplements or the antibiotic improved the growth of chicks receiving the commercial herring meals to make them comparable with those receiving the low-temperature meal.

In further tests, groups of 22 day-old White Leghorn chicks were given rations containing ground yellow maize and the herring meals, including a low-temperature one heated to 149° C. for 180 min. The superior nutritive value of the low-temperature over the commercial meal was confirmed, and subsequent heating of the low-temperature meal at 149° C. for 180 min. greatly reduced its nutritive value. The addition of 100 g. L + lysine HCl per 100 lb. feed did not improve its value.

It was further shown that when the previous vitamin concentrates or 0.25 per cent. Aurofac was added to a yellow maize ration containing 19 per cent. commercial meal, the latter had a nutritive value equivalent to the low-temperature meal. Addition of the individual vitamins in the mixture to a similar basal ration showed that folic acid at 0.0227 g. per 100 lb. feed produced a growth response only slightly less than the complete mixture. Supplements of 3 per cent. liver meal or 5 per cent. dried whey or dried cereal grass gave a growth response similar to that of folic acid. Addition of liver meal or dried brewer's yeast with folic acid had no supplementary effect over that of folic acid alone.

In all these experiments, the different herring meals had not been prepared from the same batch of fresh herring. When this was done and feeding trials were made, the results were similar.

2. The meals used in this experiment were those produced for the feeding trials just described. Amino-acids measured after enzyme hydrolysis compared with those measured after chemical hydrolysis indicated the biological availability of the compounds. On this basis there was very little difference between the lots of raw fish and the presscake or meal produced by any process except for exposure to 159° C. for 180 min. In meal so treated, the availability of all the essential acids was much reduced. The most affected amino-acids were tryptophan, lysine, methionine, threonine and valine, all of which readily take

part in the Maillard reaction. Free ribose and deoxyribosenucleic acid content were estimated and it was shown that these substances are liberated on extensive heating and combine with amino acids in the Maillard reaction to give browning in the meal.—M. J. Head.

5515

REED, J. R. (Jr.), QUISENBERRY, J. H. and COUCH, J. R. **Use of supplementary methionine at low levels in broiler rations.** *Poultry Sci.*, 1954, **33**, 41-47. [Substat. 21, Texas Agric. Exp. Stat., Gonzales, Tex.]

In each of the experiments reported, groups of 100-day-old chicks were reared in pens providing 1 sq. ft. per bird. In experiment 1 four different soya bean oilmeals, (1) solvent-extracted soya bean meal (41 per cent. protein), (2) as for (1) (50 per cent. protein), (3) overheated expeller extracted soya bean meal (41 per cent. protein), (4) a commercial expeller meal (41 per cent. protein), and (5) a mixture of (2) with equal parts of cottonseed meal (41 per cent. protein) low in gossypol, were used in compounding maize plus milo, soya bean meal type rations for New Hampshire chicks reared on sand litter. Each basal ration was duplicated with one containing a supplement of 3 per cent. fishmeal, the soya bean meal being adjusted to keep the protein level constant; each of these 10 rations was duplicated with one containing a supplement of 0.05 per cent. DL-methionine. To 10 weeks of age, the methionine supplement produced an increase in growth and feed efficiency; the increased growth rate was apparent in the presence of fishmeal but not in the groups given the overheated meal or the commercial expeller meal. Better feathering was found on the birds given methionine, even in the presence of fishmeal.

In experiment 2, a basal ration of 30 per cent. maize, 29.5 per cent. milo and 32 per cent. soya bean meal (41 per cent. protein), specially fortified with 200 mg. choline chloride per lb. feed, was given with supplements of 5, 10, 40 and 60 mg. bacitracin per lb. for the first 4 weeks, reduced to 5 mg. bacitracin per lb. to 8 weeks; 4 further groups received supplements of a bacitracin-penicillin mixture given to provide 2.5, 10, 20 and 30 mg. bacitracin and 0.5, 2, 4 and 6 mg. penicillin per lb. feed, respectively, to 4 weeks of age. All rations were duplicated with a 0.05 per cent. DL-methionine supplement. Regardless of antibiotic supplementation, the methionine improved growth and feed efficiency.

In experiment 3, the basal rations were similar to those in experiment 2 with and without 3 per cent. condensed fish solubles, each with 5 mg. bacitracin or 2 mg. procaine penicillin per lb. feed; all rations were duplicated with 0.05, 0.025 and 0.0125 per cent. DL-methionine. No improve-

ment in growth due to methionine was found, although feed efficiency was improved.

It is concluded that overall a supplement of 0.025 per cent. methionine produces nearly as much growth improvement as 0.05 per cent., but that the improvement at the 0.0125 per cent. level is not always recognisable with the type of ration used in these experiments.—M. J. Head.

5516

GORDON, R. S., MADDY, K. H. and KNIGHT, S. **Value of methionine hydroxy analogue supplementation of broiler rations.** *Poultry Sci.*, 1954, **33**, 424-425. [Dept. Res., Monsanto Chemical Co., Everett, Mass.]

Groups of day-old New Hampshire male chicks were given a basal ration of yellow maize 57, soya bean oilmeal 35 and alfalfa meal 3 per cent., with mineral and vitamin additions. The following supplements were tested: (1) 0.05 per cent. methionine hydroxy analogue, (2) 2.5 per cent. fishmeal, (3) supplements (1) and (2) together, (4) supplement (2) plus 2 per cent. whey, (5) supplements (4) and (1) together. To 10 weeks of age there was no difference in liveweight gain between the groups, but those receiving methionine hydroxy analogue showed a significantly superior feed efficiency.—M. J. Head.

5517

ALMQUIST, H. J. and MERRITT, J. B. **Relation of fiber level in mash and grain to gain and economy of Broad Breasted Bronze turkeys.** *Poultry Sci.*, 1954, **33**, 434-435. [The Grange Co., Modesto, Calif.]

Groups of from 170 to 180 14-week-old turkeys were given one of three 20 per cent. protein mashes in which the proportions of milo, maize, barley and millrun were varied to give mash fibre levels of 5.7, 6.6 and 7.5 per cent.; a choice of milo or barley grain was given in addition. All feeds were available to the groups free choice at all times. The hens were fit for the table at 24 weeks and the toms at 27 weeks of age. Both hens and toms increased the proportion of the low-fibre grain, milo, eaten as the level of fibre in the mash increased. In all cases the birds selecting milo grain grew faster than those selecting barley. After 20 weeks of age, when the grain intake was proportionately higher than before, the fibre level of the total diet was closely related to feed efficiency for toms, but not with hens until the level of 6.5 per cent. fibre in the ration was reached.

BUCKNER, G. D., INSKO, W. M. (Jr.), HENRY, A. H. and WACHS, E. F. **The comparative rates of growth and ossification of the femur, tibia and metatarsus bones of the male and**

female New Hampshire chickens having crooked keels. *Poultry Sci.*, 1954, **33**, 397-400. [Kentucky Agric. Exp. Stat., Lexington.]

The data for this study were obtained from groups of 8 male and 8 female chickens with crooked keels withdrawn from a large flock every 2 weeks from the 8th to the 28th week of age. To the 14th week of age, the percentage gain of the leg bones was similar in both sexes, although the males were heavier than the females. Thereafter the bones of the male grew rapidly to maturity at the 20th week, but the metatarsus of the female grew very little after the 14th week; the other 2 bones of the female grew most rapidly after the 20th week. The volumes of these 3 leg bones reached a maximum at the 20th week in both males and females. The ash percentage in all 3 bones in males and females varied little to the 20th week, when it began to increase in all bones but most rapidly in females. The percentage of Ca in the bone ash remained constant. A comparison of the data with that from birds with straight keels (Abst. 2936, Vol. 20) revealed no difference for any character, and in all instances males were heavier than the females.—M. J. Head.

5519

HIXSON, O. F. and ROSNER, L. Effect of unidentified factors in yeast on growth and hock disorder of turkey poults. *Poultry Sci.*, 1954, **33**, 66-68. [Laboratory of Vitamin Technology, Inc., Chicago, Ill.]

Groups of 14 or 15 three-day-old Broad Breasted Bronze female poults (Cornell University strain) were given an adequate maize and soya bean meal ration supplemented with 5 per cent. of 3 different brewer's yeasts, 2 different "primary grown" yeasts and 1 torula yeast. The groups were reared on wire floors to 8 weeks of age. The birds receiving the yeast supplement were heavier than the controls at 4 and 8 weeks but no difference was observed between the types of yeast.

In a further experiment, 7 groups of 12 day-old male chicks of the same strain were given a mixed maize, soya bean meal and casein ration supplemented with minerals and vitamins to 6 weeks of age. Six groups received a supplement of 5 per cent. yeast of the same types as in the first experiment. The incidence of enlarged hock in the unsupplemented group was 33 per cent. for the first 3 weeks, falling to 16 per cent. for the fourth, fifth and sixth weeks. The addition of the 3 brewer's yeasts and one of the primary grown yeasts considerably reduced the incidence, but the other 2 yeasts were less effective. A further group was given the basal ration with 10 mg. nicotinic acid and 40 mg. *d*- α -tocopheryl acetate per lb. feed, but this had no effect on the incidence.

M. J. Head.

COMBS, G. F., ARSCOTT, G. H. and JONES, H. L. Unidentified growth factors required by chicks and poults. 3. Chick studies involving practical-type rations. *Poultry Sci.*, 1954, **33**, 71-79. [Dept. Poultry Husb., Univ. Maryland, College Park.]

Duplicate groups of 20 chicks were fed from day-old to 8 weeks of age on a ration made up of soya bean oilmeal 36, DL-methionine 0.05, minerals 4.5, vitamin A and D oil 0.25, choline chloride, nicotinic acid, riboflavin, calcium pantothenate, vitamin B₁₂, 2-methyl-1:4-naphthaquinone and yellow maize meal to 100. They finished with a mean weight of 781 g. Three similar groups that received the same ration supplemented with 1, 2 and 4 per cent. of butyl molasses fermentation solubles had a mean weight of 855 g. Two further groups that received the original ration supplemented with 2.5 and 5 per cent., respectively, of menhaden fishmeal finished with mean weights of 855 and 840 g. Lastly, 2 groups received the original ration supplemented in each case with 2 per cent. of butyl molasses fermentation solubles and also with either 2½ or 5 per cent. of fishmeal, and their mean finishing weight was 905 g.

The results of this and of 10 further growth trials in which these and other supplements were given singly and in combination led to the conclusion that chicks require 2 unknown growth factors for rapid growth, one of which is present in animal products (fish, meat and whale), and the other in fermentation by-products and dried whey. The activity of these factors appeared, however, to be reproduced by the introduction of 10 p.p.m. procaine penicillin into the chick rations. Also it is stated that in a proportion of trials no response is obtained with sources of these "factors" even in the absence of dietary antibiotics. Orotic acid added at a level of 33 p.p.m. appeared to have a growth-promoting action independent of the postulated factors and of dietary antibiotics.

PALAFIX, A. L. and ROSENBERG, M. M. **An evaluation of low-grade sugar in starter and grower rations of chickens.** *Poultry Sci.*, 1954, **33**, 127-133. [Dept. Poultry Husb., Univ. Hawaii, Honolulu.]

Replicated groups of day-old New Hampshire chicks were given starter rations in which different amounts of a mixture of low-grade sugar and bagasse pith (10:1) was substituted for yellow maize meal. The ration containing the greatest amount of the sugar mixture (56.5 per cent.) was considered to be nutritionally adequate for normal growth. The growth rate of the chicks was inversely proportional to the amount of sugar mixture in the ration, but only those chicks given 56.5 per cent. sugar mixture were significantly smaller than the controls. Efficiency of feed conversion was also inversely proportional to the proportion of sugar mixture in the ration. Chick mortality rate was not affected by the feeding of the sugar mixture.

In trial 2, 48, 40 and 32 per cent. sugar mixture was substituted for yellow maize meal in the chick rations, but the proportions of herring meal and soya bean meal were adjusted to equalise the protein contents of the rations. Here the higher levels of the sugar mixture had no adverse effect on growth but birds receiving 32 per cent. sugar mixture were significantly smaller than the controls. Efficiency of feed conversion increased with an increase in the proportion of sugar mixture. Chick mortality was unaffected.

In trials 3 and 4, the experimental rations were given from the seventh to the fifteenth week of life to groups of 8-week-old New Hampshire cockerels housed in open-air wire-floor pens. In trial 3, groups of 17 birds were given rations containing up to 58.5 per cent. low-grade sugar in direct substitution for yellow maize meal. Only the group receiving the highest level grew significantly more slowly than the controls. The feed efficiency was inversely proportional to the concentration of sugar in the ration and there was no effect on mortality rate. The rations given in trial 4 to groups of 18 New Hampshire cockerels were similar to those in trial 3 except that the mixture of low-grade sugar and bagasse pith (10:1) was used instead of low-grade sugar alone. The birds given 19.5 or 39 per cent. sugar mixture grew at a rate similar to that of the controls, but those receiving 58.5 per cent. of the mixture grew significantly more slowly, and the feed efficiency

decreased as the proportion of sugar mixture in the ration increased.—M. J. Head.

5525

ROSENBERG, M. M. **An evaluation of B-grade molasses in chick starter rations.** *Poultry Sci.*, 1954, **33**, 382-389. [Dept. Poultry Husb., Univ. Hawaii, Honolulu.]

Duplicate groups of 20 day-old New Hampshire chicks housed in batteries were used.

In trial 1, the basal ration contained yellow maize 54, herring meal 10, soya bean meal 30 and alfalfa meal 3 per cent., supplemented with minerals and vitamins. A mixture of B-grade molasses and bagasse pith (5:1) was added at levels of 13.5, 27, 40.5 and 54 per cent. in direct substitution for yellow maize to give calculated protein levels in the ration of 25.7 per cent. for the control and 24.4, 23.2, 22.0 and 20.8 per cent., respectively, for other groups. At 21 days of age, all birds receiving the sugar mixture were smaller than the controls, but only those receiving the largest amount significantly so; feed efficiency was also lower than for controls on all the sugar rations and significantly so at the highest rate of substitution. At 6 weeks of age, the birds receiving 40.5 or 54 per cent. of the sugar mixture were significantly smaller than the controls, and the feed efficiency of all groups receiving the sugar mixture was significantly lower than for controls.

In trial 2, the basal ration was similar to that in trial 1, with the omission of herring meal. The sugar mixture was directly substituted for yellow maize meal at 32, 40 and 48 per cent., but small amounts of herring meal and soya bean oilmeal were given in addition to equalise the protein contents of the rations, at 20.3, 20.5 and 20.2 per cent., respectively; the basal ration contained 22.2 per cent. No significant difference in group chick weights was found although chicks receiving 48 per cent. sugar mixture had a lower feed efficiency.

In trial 3, graded amounts of herring meal and soya bean oilmeal were included in all rations. B-grade molasses was given at levels of 23.0, 29.5, 37.0 and 46 per cent. and at each level a low (over 37 to 1) and a high (5 to 1) level of bagasse pith was given. At the low levels of bagasse pith wheat bran was added. At 3 weeks of age all chicks had grown well but at each level of molasses intake those receiving the low level of bagasse pith with bran grew faster than the controls and those receiving the 5:1 mixture. Feed utilisation was best in groups receiving the low levels of bagasse pith. At 6 weeks of age, the male chicks receiving the normal 5:1 mixture were significantly lighter than the other birds at each molasses level; there was no comparable effect on the females.

BROWN, W. O. **The effect of antibiotics on the growth rate of chicks fed high quality diets.** *Res. Exp. Rec. Minist. Agric. N. Ireland*, 1952, 54-59. [Minist. Agric. N. Ireland.]

Duplicate groups of Light Sussex pullet chicks were reared on litter in a brooder house and fed to 8 weeks of age on a ration (A) made up of livermeal 10, fishmeal 5, groundnut meal 5, cod liver oil 2, limestone 1, wheat feed 25, ground barley 15 and maize meal to 100; their mean weight gain was 775 g. Further groups fed on a similar ration (B), with the livermeal replaced by dried skimmed milk and the level of fishmeal increased to 10 per cent. at the expense of maize meal, had a mean gain of 795 g. Parallel groups receiving rations A and B each supplemented with 20 g. [misprinted as 4.0 g. in Table IV] procaine penicillin per ton had mean weight gains of 870 and 945 g., respectively. This mean increase of 15 per cent. in growth rate with the antibiotic was accompanied by a 10 per cent. improvement in efficiency of feed utilisation despite the high quality of the basal rations.

In two further trials, one in wire-floored cages and one using floor pens, there was a tendency for both terramycin and procaine penicillin, both used at a level of 4 g. per ton of feed, to increase growth by about 7 per cent., but the differences were not statistically significant with the numbers used.

5527

SLINGER, S. J., PEPPER, W. F. and HILL, D. C. **High levels of antibiotics and white feathers in poults.** *Poultry Sci.*, 1954, 33, 211-212. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

A group of 20 Broad Breasted poults was fed to 4 weeks of age on a mash which included 6 per cent. of animal protein concentrates, 43 per cent. of soya bean meal and supplementary methionine, nicotinic acid and vitamin B₁₂. The mash showed, on analysis, 28.4 per cent. crude protein and 1.63 per cent. lysine. At 4 weeks of age the poults had a mean liveweight of 504 g., the feed to gain ratio was 1.91, and no case of white barring of the feathers was seen.

Three parallel groups received the same ration supplemented with procaine penicillin at levels of 4, 20 and 80 p.p.m., respectively. Their mean finishing weights were 550, 568 and 567 g. and the corresponding feed to gain ratios were 1.79, 1.64 and 1.74. Three further groups received aureomycin in their rations at levels of 10, 50 and 200 p.p.m., respectively, and finished with mean weights of 564, 606 and 568 g., and feed to gain ratios of 1.79, 1.60 and 1.63. None of the birds receiving an antibiotic showed white barring.

It is suggested that field reports of "white barring" as a result of the introduction of anti-

biotics into poult starting rations may be explained if the rations contain less lysine than in the present experiment, the lysine being then insufficient for the increased growth rates obtained with the antibiotics.—K. J. Carpenter.

5528

MACGREGOR, H. I., BLAKELY, R. M. and ANDERSON, R. W. **Antibiotics in the diet of turkey poults of various ages.** *Poultry Sci.*, 1954, 33, 36-38. [Dominion Exp. Stat., Swift Current, Sask.]

Two groups of day-old Broad Breasted Bronze poults were reared on an adequate practical ration, one group receiving 8.8 p.p.m. procaine penicillin in addition. At 8 weeks of age the birds were divided into 2 groups on the basis of corresponding weights, both groups being given an all-mash ration at pasture and one group receiving 4 p.p.m. procaine penicillin in addition. The mash was modified every 4 weeks to provide a decreasing amount of protein.

The addition of penicillin to the growing diet increased the growth rate of female poults which had received the antibiotic in the rearing stage. There was no effect on other groups to 20 weeks of age.—M. J. Head.

5529

WISMAN, E. L., BOUCHER, R. V. and CALLENBACH, E. W. **The influence of combining and interchanging antibiotics in chick diets.** *Poultry Sci.*, 1954, 33, 290-293. [Pennsylvania Agric. Exp. Stat., State College.]

A group of 26 chicks was housed in a wire-floored cage and fed to appetite to 10 weeks of age on a dry ration of soya bean meal 20, maize gluten meal 5, dried whey 3, dried yeast 3, choline chloride 0.12, alfalfa meal 2.5, vitamin B₁₂, riboflavin, minerals and yellow maize meal to 100. Their mean live-weight gain was 1230 g. and they used 2.86 g. feed per g. gain.

Five parallel groups received the same ration supplemented with 5 g. of an antibiotic per ton. This was either procaine penicillin, terramycin hydrochloride, a mixture of the two, or first one for 3 weeks and then the other. The mean gains of these groups ranged from 1383 to 1428 g., and the feed conversion rates from 2.47 to 2.63. Less favourable results were obtained, in general, in further groups where streptomycin was used, either by itself or in combination with one of the other antibiotics.

It is concluded that penicillin, terramycin, or a combination of the two at a total level of 5 g. free base per ton feed, is equally effective.

WISMAN, E. L., BOUCHER, R. V. and CALLENBACH, E. W. **The influence of an antibiotic, animal**

N.A. and R., October 1954

protein, sex and rearing environment on chick growth. *Poultry Sci.*, 1954, **33**, 328-332. [Pennsylvania Agric. Exp. Stat., State College.]

This was a $2 \times 2 \times 2 \times 2$ factorial experiment in which 8 groups of 25 sexed New Hampshire chicks were housed in wire-floored brooders and 8 groups of 75 New Hampshire chicks in colony houses with shavings for litter. The animal protein ration contained fishmeal 5, meat scrap 2, bonemeal 0.75 and soya bean oilmeal 13 per cent.; the plant protein ration contained only soya bean oil meal 19.8 and bonemeal 2.2 per cent.; each ration contained 3 per cent. dried whey. The rations were given with or without 20 g. terramycin hydrochloride per ton of feed.

Each treatment had an effect; that is, chicks reared in batteries, male chicks, chicks given the animal protein ration and chicks given terramycin were significantly heavier at 12 weeks of age. Chicks receiving animal protein were heaviest when they were male, reared in a battery and not given antibiotic. Animal protein or terramycin produced comparable growth responses when added to the plant protein ration and the effect of both together was greater than that of either singly. There was no effect of sex on terramycin-induced gains, which were greatest in the early stages of growth and gradually decreased. Feed utilisation data are presented [but with no statistical analysis].

Data on variability of chick growth showed it to be greater in colony houses than in brooders, in males than in females, and in chicks receiving animal protein.—M. J. Head.

5531

ATKINSON, J. C., BOUCHER, R. V. and CALLENBACH, E. W. **The influence of terramycin and aureomycin on growth, variability, and efficiency of feed utilization in White Holland turkeys.** *Poultry Sci.*, 1954, **33**, 332-344. [Pennsylvania Agric. Exp. Stat., State College.]

A large control group (1) of turkey poults was reared in a wire-floored battery cage to 6 weeks of age, then transferred to a floor pen for 2 weeks, and finally to bluegrass range for 20 weeks. Up to 8 weeks of age the poults received a ration containing 25 per cent. crude protein and including 5 per cent. fishmeal, 4 per cent. dried whey and 4 per cent. dried yeast; after this time they received a ration containing 17 per cent. crude protein, with no fishmeal and 1 per cent. each of dried whey and dried yeast. Further groups received the same management and similar rations fortified with 4.5 g. aureomycin hydrochloride per ton either for the whole period (group 2) or for the first 8 weeks only (group 3).

At 8 weeks of age the mean weights in group 1 were 960 g. for females and 1150 g. for males; the corresponding means in the supplemented groups

were approximately 10 per cent. more for each sex. At 28 weeks the mean weights in group 1 were 11.0 lb. for females and 18.0 lb. for males, in group 2, 11.2 and 18.5, and in group 3, 11.3 and 17.2 lb. Statistical analysis showed no effect of treatment on the final weight of the females, and an improvement for males only when supplementation was continued after the eighth week. The individual weights were as variable in the supplemented groups as in the control group; and the proportion of deaths did not differ significantly between groups.

In two further experiments poults were taken only to 8 weeks of age, and at this point birds that had received a supplement of 4.5 g. terramycin hydrochloride per ton were from 4 to 10 per cent. heavier than control birds. In one trial 9.0 g. gave a greater effect than 4.5 g. per ton, and in the other 2.25 g. given to one group appeared more effective than 4.5 g. per ton given to another group.

Effects on efficiency of feed utilisation were smaller than the effects on rate of growth.

MARCH, B. E., BURDETT, M. and BIELY, J. **Antibiotics and surface active agents in chick nutrition.** *Poultry Sci.*, 1954, **33**, 300-304. [Poultry Nutrit. Lab., Univ. British Columbia, Vancouver.]

Duplicate lots, each of 20 chicks, were fed to 8 weeks of age on a ration of soya bean meal 13.4, herringmeal 6.7, liver meal 3, dried distiller's solubles 2, dried grass, bonemeal and other mineral supplements, vitamin A and D oil, nicotinic acid, choline chloride and equal parts of maize and wheat to 100; their mean finishing weight was 750 g. Parallel groups received the same ration supplemented with 1 per cent. of Tween-80 (polyoxyethylene sorbitan mono-oleate) and finished with a significantly heavier mean weight of 824 g. Further groups received the original ration supplemented with 3.3 p.p.m. procaine penicillin and had a mean weight of 835 g.

In a second trial chicks were fed to 4 weeks of age on a simplified maize and soya bean mixture fortified with minerals, vitamins A and D, choline, nicotinic acid, riboflavin and pantothenic, but not folic acid; their mean weight was 229 g. Other groups received the following supplements (mean weights in g. in parenthesis): 0.5 per cent. of Tween-80 (248), 0.8 p.p.m. folic acid (356), Tween-80 and folic acid (364), 3.3 p.p.m. procaine penicillin (359). Another test supplement, Santomerse-80 (an alkyl aryl sulphonate compound), used at a level of 0.1 per cent., gave chicks with a mean weight of 296 g.; when it was used in combination with folic acid the chicks weighed 384 g., and with penicillin 373 g.

In a third trial chicks were fed to 9 weeks of age on a series of rations each with and without the addition of 0.2 per cent. of Santomerse-80. On the basal ration, similar to that used in trial 1, the mean finishing weight was 775 g., and with the Santomerse-80 supplement it was 841 g. When procaine penicillin was also incorporated in the rations the corresponding weights were 850 and 841 g. On the basal ration supplemented with 2.5 to 7.5 per cent. of herring oil group weights ranged from 850 to 900 g., but on the same rations supplemented with Santomerse-80 the birds were no heavier, nor did the addition of Santomerse-80 further stimulate the growth of chicks receiving rations containing both herring oil and procaine penicillin.

In the last trial the addition of 0.1 per cent. of Santomerse-80 failed to stimulate the growth of chicks fed to 8 weeks of age on a ration similar to that previously used, but of higher protein content, whether it was supplemented with herring oil or not.

It is concluded that some of the differences in growth response arising from the introduction of surface-active agents into chick rations are related to differences in the composition of the basal rations used.—K. J. Carpenter.

5533

REID, B. L., ELAM, J. F. and COUCH, J. R. **The effect of oral and parenteral administration of antibiotics on growth and fecal microflora in the turkey poult.** *Poultry Sci.*, 1954, **33**, 307-309. [Dept. Poultry Husb., Texas Agric. and Mech. Coll. System, College Station.]

A group of 20 poults was reared to 10 weeks of age in a wire-floored cage and fed on a ration containing soya bean meal 60, mineral supplements 5, vitamin A and D oil, riboflavin, pantothenic acid, nicotinic acid, vitamin B₁₂ and maize-meal to 100; the mean finishing weight was 2050 g. Parallel groups receiving supplements of penicillin, aureomycin and bacitracin, each at a level of 33 p.p.m., weighed 2290, 2320 and 2391 g., respectively. Further groups receiving 4 mg. per bird weekly of these antibiotics by injection weighed 2190, 2460 and 2210 g., respectively.

Samples of excreta were taken from each cage at weekly intervals and bacterial counts were made by a technique previously reported (Abst. 3518, Vol. 21). Although the injection of aureomycin appeared to have the greatest effect on growth it had no detectable effect on the total dilution count, or on the numbers of enterococci, lactic acid bacteria or yeasts in the excreta. However, the group receiving these injections did give droppings with a greater number of aureomycin-resistant organisms than were found in the droppings from the control group.

The birds receiving injections of penicillin showed no detectable difference from the controls in their faecal counts, although differences had been reported in earlier papers (Abst. 1428, Vol. 22). The increased growth obtained in the present experiment with penicillin injection was not, however, considered to be significant.

K. J. Carpenter.

5534

ELAM, J. F., JACOBS, R. L., FOWLER, J. and COUCH, J. R. **Effect of dietary *Clostridia* upon growth-promoting responses of penicillin.** *Proc. Soc. Exp. Biol. Med.*, 1954, **85**, 645-648. [Dept. Poultry Husb., Texas Agric. Exp. Stat., College Station.]

For a feeding experiment with chicks from hatching to 10 weeks of age 2 rooms were used. A "clean" room was washed daily for 2 weeks before and throughout the whole period of the trial, and another "old" room was one that had been used continuously for chicks for 3 years and not specially prepared. Battery cages with raised wire floors were used in both. In the "old" room one group of chicks that received a control all-vegetable diet finished with a mean weight of 969 g. and a further group that had the same diet supplemented with 4.4 mg. penicillin per kg. finished with a mean weight of 1085 g. Similar groups that received these treatments in the "clean" room weighed 1167 and 1210 g., respectively.

Further groups in the clean room received diets supplemented with chick excreta that had been heated to kill aerobic organisms, at a level contributing about 90,000 clostridia per kg. diet. With this supplement alone the mean group weight was 1042 g. and with penicillin in addition it was 1180 g. A final group given a supplement of excreta that had been autoclaved to destroy all the micro-organisms weighed 1150 g. per head.

Samples of excreta were obtained weekly from the experimental groups, and their content of clostridia was ascertained. The control group in the "old" room gave excreta from which 16,000 were obtained per g.; the corresponding group in the "new" room gave 1200. The comparable figures for the penicillin-supplemented groups were 270 and 620, respectively. The dietary supplement of excreta in the "clean" room gave droppings in turn from which 10,000 per g. were obtained; but with penicillin in addition only 450 were counted.

Since similar results were obtained in a second trial, it was concluded that the depressed growth of chicks in "old" quarters may be at least partly due to a "build-up" of clostridia in their intestinal tract, and that the growth-promoting effect of penicillin by mouth may be associated with its action in reducing the numbers of these organisms.

BEGIN, J. J. and THORNTON, P. A. **Response of hormone-injected New Hampshire chickens to antibiotic supplementation.** *Poultry Sci.*, 1954, **33**, 212-214. [Kentucky Agric. Exp. Stat., Lexington.]

Eight groups of 8 male and 8 female day-old chicks were given a maize and soya bean oilmeal ration with or without 10 mg. bacitracin per lb. feed. At 4 and 38 days of age, 4 males from each group were given a 20 mg. tablet of diethylstilboestrol subcutaneously in the neck and 4 females of each group had 20 mg. testosterone propionate similarly administered. Without the hormone, bacitracin feeding produced a 5 per cent. smaller gain in females and a 7 per cent. greater gain in males. All birds that received the hormone grew more slowly than the controls and the effect of bacitracin on these birds was similar to that in the untreated birds. The dose of hormone was sufficient to modify the secondary sex characters, but not to modify the differential sex response to antibiotic supplementation.—M. J. Head.

BOBBY, F. C. and BELWORTHY, W. R. **Advantages of chemical caponisation of cockerels.** *N.Z. J. Agric.*, 1954, **88**, 19-21. [Poultry Demonstration Plant, Upper Hutt.]

Australorp × White Leghorn cockerels were caponised surgically or by stilboestrol implantation, and a group was left intact as controls. They were fed to 26 weeks on a grain and mash ration. They were weighed monthly, and feed intake was measured. Some birds were killed at 21 weeks old.

Caponisation by either method significantly improved carcase quality, but there was no difference between the methods. The advantage of implantation was that there was no danger of birds dying as a result of the operation, and no temporary set-back in growth. The quality of the caponised carcasses deteriorated from the 21st to the 26th week. Capons ate about 5 lb. more feed and weighed about $\frac{1}{2}$ lb. more than the intact cockerels.—T. D. Bell.

PEPPER, W. F., SLINGER, S. J. and BERGEY, J. E. **Effect of 3-nitro, 4-hydroxyphenylarsonic acid on the growth and sexual maturity of pullets.** *Poultry Sci.*, 1954, **33**, 422-423. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

Two groups of 197 Columbian Rock female chicks were given adequate starting, growing and laying rations to appetite, with or without 45 g. 3-nitro-4-hydroxyphenylarsonic acid per ton of feed. The wood-shaving litter in the brooder and laying house pens was changed once in 10 weeks. Group chick weights were obtained at 6, 10 and 15 weeks of age and the birds were weighed individually at 20 weeks of age. The average live-weights of the chicks in the control and supplemented groups were 466 g., 1066 g., 3.39 lb. and 4.44 lb. and 562 g., 1188 g., 3.69 lb. and 4.73 lb., respectively, at these ages. The drug had no effect on mortality. Birds from both groups began laying during the 19th week, but by the end of the 20th week the supplemented group had produced 94 eggs, compared with 30 eggs for the control. Full data for egg production and hatching will be published later.—M. J. Head.

5539

NEX, L. F. and NEWELL, G. W. **The effect of a sodium alkyl aryl sulfonate detergent on the growth of chicks.** *Poultry Sci.*, 1954, **33**, 297-299. [Dept. Biol., Stanford Res. Inst., Calif.]

The basal ration used with day-old chickens was of yellow maize, soya bean oilmeal, alfalfa meal and fishmeal, with distiller's solubles, dried whey and minerals. The addition of a commercial Na alkyl aryl sulphonate detergent, at the rate of 2.0 g. active substance per kg. feed, produced a rate of growth to 12 weeks significantly higher, by 11 per cent., than that of unsupplemented controls. Addition of procaine penicillin, 3.3 mg. per kg., to the basal ration produced an earlier stimulation of growth than the detergent but at 12 weeks gains were similar. Phenylarsonic acid, 0.9 g. per kg., also significantly increased rate of growth. In each case feed conversion ratio was improved.

BRANION, H. D. and HILL, D. C. **Detergents and chick growth.** *Poultry Sci.*, 1954, **33**, 62-66. [Dept. Nutrit., Ontario Agric. Coll., Guelph.]

Triplicate groups of 13 or 14 newly hatched Columbian Rock female chicks were reared on a wire floor for 12 weeks and given a basal ration containing 23 per cent. protein with a detergent supplement. The detergents were given as 0.5 per cent. of the ration and 10 p.p.m. procaine penicillin were given to one group. In experiment 1, the detergents used were Vel, Tide, Surf and

Dreft and in experiment 2 Fab, Duz [Daz?] and Rinso. Neither the detergents nor the antibiotic had any effect on liveweight compared with the controls at 14-day intervals to 12 weeks of age. Mortality was almost zero in both experiments. Theories of the possible mode of action of surface-active substances in other reported experiments are discussed.—M. J. Head.

SLINGER, S. J., PEPPER, W. F. and MORPHET, A. M. **The prevention of perosis in turkeys with 4-nitrobenzenearsonic acid.** *Poultry Sci.*, 1954, **33**, 214-215. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

Two groups of 50 male and 50 female day-old Broad Breasted Bronze poults were assigned to groups by weight, brooded in colony houses with wood shavings as litter, and reared from the eighth to the twentieth week of age in slatted sun porches. The basal starting and growing rations contained animal protein and were given with and without 0.025 per cent. 4-nitrobenzenearsonic acid in the mash; as the growing poults received oats as scratch grain, the level of the drug was lower than 0.025 per cent. in the total ration. At 8 and 16 weeks of age there was no difference between the groups in liveweight, but at 20 weeks of age the males receiving the drug weighed significantly less than the controls. It is suggested that the difference in the effect of the drug over the age range may be accounted for by the limited access to droppings after 8 weeks of age. Perosis occurred only in the males on the control ration at 16 and 20 weeks of age, 17.7 and 25.5 per cent., respectively, being affected.—M. J. Head.

5544

HEYWANG, B. W. and BIRD, H. R. **The effect of alfalfa saponin on the growth, diet consumption and efficiency of diet utilization of chicks.** *Poultry Sci.*, 1954, **33**, 239-241. [Agric. Res. Admin., U.S. Dept. Agric., Bur. Animal Indust., Glendale, Ariz.]

In duplicate experiments groups of 10 day-old New Hampshire chicks were given a ration of

maize and soya bean oilmeal with or without 0.05, 0.10, 0.20 and 0.40 per cent. alfalfa saponin for the first 6 weeks of life; in the second experiment one group received 0.15 per cent. alfalfa saponin. In experiment 1, the chick liveweights at 6 weeks of age were 706, 692, 695, 618 and 518 g. and the efficiencies of feed conversion 0.478, 0.471, 0.478, 0.462 and 0.440, respectively. In experiment 2, the corresponding chick weights and efficiencies were 701, 692, 678, 678, 605 and 439 g., and 0.420, 0.423, 0.408, 0.423, 0.409 and 0.383. Feed consumption of the groups receiving the higher levels of saponin was about 200 g. less than that of the control chicks. No chick died in this experiment from saponin feeding and the highest level was equivalent to the inclusion of 50 per cent. alfalfa in the ration. Hence it is considered that saponin is not the only substance in alfalfa which has an undesirable effect on chick growth.—M. J. Head.

5545

DARROW, M. I. and STOTTS, C. E. **The influence of debeaking broilers upon growth rate, feed utilization, and market quality.** *Poultry Sci.*, 1954, **33**, 378-381. [Res. Labs., Swift and Co., Chicago, Ill.]

The data reported came from 10 field tests with over 14,000 birds on each treatment in 3 different broiler-producing areas in the United States. At 3 weeks of age, the birds had one-third to one-half of the upper beak removed by conventional electric debeaking equipment. The treated and normal birds were kept in separate halves of the same house. A mash with 21 per cent. protein, or pellets and mash, was given to all.

The average weight of the treated broilers in the 3 regions was 2.76, 3.20 and 2.83 lb. and of the normal broilers 2.77, 3.17 and 2.88 lb., respectively, giving an overall average weight of 2.91 lb. for the treated birds and 2.92 lb. for the control birds. In 7 tests the treated birds ate 0.1 lb. less feed per 1 lb. gain than the control normal birds; there was no difference in the remaining 3 tests. The improvement in efficiency of use of feed is attributed to less scattering of the feed. Feathering was better than average in all flocks; even so, 83 per cent. of the treated birds gave grade A carcasses compared with 73 per cent. of the controls.

In further experiments at 4 centres with White American, White American × White Rock, Delaware × New Hampshire and White Rock × New Hampshire breeds, the rates of growth and mortality in a group of 50 chicks debeaked electrically at 1 day old were compared with those of normal chicks. No difference in liveweight at 3 or 8 weeks of age was found and mortality was low in all groups.—M. J. Head.

5546

OLSSON, N. Korsnings- och uppfödningförsök med gäss. [**Crossbreeding and raising of geese.**] *Kgl. Lantbrukshögsk. Statens Husdjursförsök Medd.* No. 53, 1953, pp. 24. English summary.

The data refer to Swedish (Skåne) geese, Toulouse and Italian geese and crosses. Mean egg yields for the pure breeds in that order, over the laying season, were 20.8, 32.2 and 36.4. Hybrids approximated to or exceeded the yield of the more prolific parent. Fertility as a percentage of eggs laid was 33.3, 71.5 and 89.4 for pure breeds. Eggs from first crosses and hybrid birds were fertile. Of fertile eggs, the following percentages hatched: 29.8, 41.3, and 68.6; the hybrids did not always do better.

Statistical analyses are presented of all these data, and the relation of day-old gosling weight to egg weight.

Rates of growth from hatching to 140 days are shown in tables and graphs, with data for feed consumption during fattening (10.63 kg. oats per kg. weight gain), slaughter losses, and the relation of loss in feathers and in bleeding to slaughter weight. Slaughter weights of the purebred birds, male and female, in the same order as above, after a 12-hr. fast, were approximately 8.8 and 6.6, 7.2 and 6.0 and 5.5 and 5.0 kg.—I. Leitch.

5547

MORLEY, F. H. W. and SMITH, J. (with FORGE, R. M. and MASTERS, F.) **A comparison between reciprocal crosses of Australorps and White Leghorns.** *Agric. Gaz. N.S.W.*, 1954, 65, 17-21.

Comparisons were made between 399 progeny of White Leghorn males and Australorp females (W/B) and 512 progeny of the reciprocal cross (B/W). The birds came from 3 different sources.

Average results were as follows for W/B and B/W cross progeny, respectively: early mortality 6.7, 4.9 per cent., weight at 11 weeks 1.52, 1.64 lb., age at first egg 181, 191 days, adult mortality from housing to 50 days, 27, 18 per cent., broodiness 17, 55 per cent. broody and 0.33, 1.64 times broody, egg weight 58.0, 57.7 g., adult bodyweight (at 500 days) 4.43 (258 survivors), 4.64 (387 survivors) lb., survivors' 500-day production 131, 116 eggs, average group production 105, 103 eggs.

Further investigation on some of these findings is in progress.—P. C. Jowsey.

See also Absts. 4335, 4358, 4398, 4444, 4471, 4472, 4525, 4529, 4542, 5018.

EGG PRODUCTION

5548

O'NEIL, J. B. **Concentrate pellets and whole grain as a method of feeding laying hens.** *Canad.*

Vol. 24, No. 4

J. Agric. Sci., 1954, 34, 131-136. [Dept. Poultry Husb., Univ. Saskatchewan, Saskatoon.]

In egg production, efficiency (lb. feed per dozen eggs laid) and general health, there was no difference between 4 groups of New Hampshire × Barred Plymouth Rock pullets of which group 1 received a commercial concentrate mash to appetite and whole grain twice daily; group 2 was fed like group 1 but was given the same amount of grain in one feed daily; group 3 had an all-mash ration in which the grain was ground and incorporated with the concentrate, and group 4 was fed to appetite with the concentrate in pellet form and mixed with the whole grains. In all groups the ratio of concentrate to grain was 1:7. Economic advantages claimed for the new method (group 4) are that the grain is not ground or hand-fed and the ration is easily mixed. The effect of the method on hatchability is being studied, and so far the results have been satisfactory.—T. D. Bell.

SKALLER, F. **Studies on the assessment of egg production in poultry breeding investigations.** 1. The optimal period for recording first year egg production. 2. The correction of hatching date for early selection based on part-annual egg production records. *Poultry Sci.*, 1954, 33, 29-35; 316-321. [Poultry Res. Centre, Werribee, Victoria.]

1. The data come from a statistical examination of the first year laying records of a sample, stratified for hatching date, of 200 birds from a flock of 1375 White Leghorn pullets. Critical examination of the existing methods for measuring the number of eggs laid in the first year, namely, by biological pullet year, by biological calendar year and by the 500-day test, showed all to be significantly influenced by hatching date. A new interval, known as the standard pullet year, is substituted and is shown to be uninfluenced by date of hatching. The number of eggs laid by the bird is measured from the first one to 31 March in the following year (southern hemisphere seasons). It is suggested that a combination of the standard laying year and the 500-day test could be used to facilitate the investigation of problems of management.

2. The data presented in this paper come from a statistical examination of the records of a sample of 200 birds from a larger flock. (All dates and seasons apply to the southern hemisphere.) In order that the records of one year's laying could be used to select birds for breeding in the second year, it was found that records must be terminated at 31 May, since mating takes place soon afterwards for hatching in early July. As the hatching

season is spread over several weeks, 9 weeks for this particular flock, the production of different birds would be recorded for different times. The need for correction for this when annual part records are used is clear. The corrected egg number is given by the formula $E_{ij} (P_{ij} - N_{ij}) / P_{ij}$, where E_{ij} is the number of eggs from first egg to 31 May for the i th bird in the j th hatch, P_{ij} is the number of calendar days from first egg to 31 May and N is the mean deviation of net potential laying days from those of the median hatch. An example is shown in the text. The correlation coefficient between part-winter records and egg numbers per standard pullet year was improved from 0.308 to 0.494 by correcting the part-winter number of eggs as described.—M. J. Head.

5550

LILLIE, R. J. and SIZEMORE, J. R. **Effect of antibiotic on egg production of New Hampshires.** *Poultry Sci.*, 1954, **33**, 427-429. [Bur. Animal Indust., Agric. Res. Admin., U.S. Dept. Agric., Beltsville, Md.]

A flock of New Hampshire birds was housed intensively for the first 7 months of egg production and fed on an all-vegetable ration of soya bean meal 20, alfalfa meal 5, butyl fermentation solubles 0.5, mineral supplements 7.5, vitamin A and D feeding oil 0.3 and yellow maize meal to 100. The pullets were trap-nested, and at the end of this period 40 which had given less than 50 per cent. production were divided into 2 groups, of which one continued to receive the same ration, and the other a similar ration fortified with 1 per cent. of a supplement containing an unstated quantity of vitamin B₁₂, and an unstated quantity of an [unspecified] antibiotic. In the period from 1 to 6 months after the segregation the supplemented group gave 40 per cent., and the unsupplemented group 28 per cent. production.

Ninety-two pullets that had given more than 50 per cent. production in the first 6 months were divided into 4 groups which received, respectively, the original ration, the original supplemented with 1 per cent. of the supplement (as above), the original ration supplemented with 0.1 per cent. of a supplement containing an unstated quantity of vitamin B₁₂ but no antibiotic, and a commercial ration [composition not stated, but reported to contain some fishmeal]. Mean egg production in the 4 groups from 1 to 6 months after the re-grouping was 56, 50, 47 and 47 per cent., respectively.

It was concluded that incorporation of a supplement of vitamin B₁₂ and an antibiotic into a laying ration improved the egg production of low producers but not that of high producers.

MEHNER, A. Versuche über die Bedeutung des Auslaufes für die Geflügelhaltung. [Importance of runs in poultry keeping.] *Arch. Geflügelk.*, 1954, **18**, 123-140. [Hohenheim.] English summary.

Two series of laying trials were made with groups of 30 laying birds. In the first, 2 groups were confined to houses, one receiving 1 g. cod liver oil per bird daily, and the 2 other groups had free access each to 240 sq. m. of meadow. All birds received daily 50 g. of a mixture of equal parts of milo, maize and oats and free access to a mash. In the second trial there were 5 groups, 3 confined to houses and 2 with access to runs. All groups received grain as above and free access to a mash. Group 1 had a mash with adequate animal protein; group 2 this mash with half the fishmeal replaced by soya bean meal; group 3 was fed as group 2 but with one-third of the soya bean meal replaced by dried whalemeal; groups 4 and 5 received the same mash as group 2.

In the first trial there was no significant difference in the weight of eggs per bird between the groups, but in the second trial the relative weights were 100, 90, 84, 145 and 136 for the 5 groups. In both trials much less mash was eaten by the birds on grass. It is calculated that in a well covered run a bird finds daily 0.5 g. animal protein per sq. m. (cf. Abst. 3704, Vol. 11). The 2 trials taken together showed a favourable effect of free run on egg production, and incubator trials showed an improvement in hatching as compared with eggs from birds confined to houses.

Calculations based on saving in feed, increase in egg production, diminution in loss of birds and increased hatch showed that the total effect of the area usually available as range for a single bird, expressed in money value, was about equal to the feed costs for a single bird for 1 year in a house.

OTHER BIRDS

5554

DEMENT'EV, G. P., KARTESHEVA, N. N. and SOLDATOVA, A. N. Pitanie i prakticheskoe znachenie nekotorykh khishchnykh ptits v yugozapadnoi Turkmenii. [The nutrition and practical importance of certain predatory birds in South-west Turkmen.] *Zool. Zh.*, 1953, **32**, 361-375. [Biol. Pochven. Inst., Mosk. Gosud. Univ. Im. Lomonosov.]

Lists are given of the food of *Bubo bubo omissus*, *Athene noctua bactriana*, *Aquila chrysaetus fulva*, *A. rapax orientalis* and *Corvus corax ruficollis*. The results showed that all these birds are useful because they prey on rodents and harmful insects in south-west Turkmen. Their numbers, however, are small and measures should be taken to protect them so that they may multiply.—W. Hughes.

FOOD ECONOMICS AND STATISTICS

5555

PEUNKOV, S. I. Proizvodstvo kumysa v usloviyakh tabunnogo konevodstva uzbekistana. [The production of koumiss under conditions of range management in horse breeding in Uzbekistan.] *Konevodstvo*, 1953, No. 3, 37-38.

European labour force has increased steadily. The extent of mechanisation has also risen, especially the number of tractors, with a corresponding decrease in the use of equines. Fencing and fertilisers are the main necessities. The brief survey indicates the profound nature of the economic, technological and social changes being experienced in South Africa.

5556

FOX, F. W. The agricultural foundation of nutrition. 3. Natural limitations to the production of food. 4. Some other basic aspects of food production. 5. Maize. *S. African Med. J.*, 1954, **28**, 267-268; 361-363; 441-444. [S. African Inst. Med. Res., Johannesburg.]

For Parts 1 and 2 see Abst. 3594, Vol. 24.

3. South Africa is better adapted to pastoral than to arable farming but it is upon its arable farming that a country ultimately depends and the extension of arable farming is limited by topography, soil type and moisture supply. Of these lack of moisture is the most important, and the conclusion is that "the bulk of our food is grown in portions of an area that is about one-fifth of the Union". The occurrence of droughts and the high evaporation rates explain the smallness of the area under cultivation. The magnitude of the Union's long-term food problems should be constantly in mind.

4. These aspects concern production by European farmers only.

Farms have increased since 1930 from 97,000 to 119,000 in 1952, but average size has decreased from 1000 to 850 morgen (1 morgen = 2.116 acre). European farming population has decreased in the same period both in actual numbers and in proportion to the total population, but the non-

5. Production statistics show that between 1918 and 1952 maize crops rose from 16 to about 28 million bags per annum. European farmers grew much more than did African, but the fluctuations, which resulted in the main from climatic variations, were greater for European than for African production. Consumption over the same period increased from 9 to 16 million bags per annum; since 1940 there has been a great rise in the amount used to feed animals. The estimate of requirement for 1972, 38.5 million bags, raises the question of how it will be met.

Increases in African production are considered unlikely and the solution must be sought on European farms. With little additional suitable land available, and if the fertility of marginal land is to be maintained, the increase will have to be in yield per morgen. Between 1918 and 1952 there has been an increase but the national average of 5.4 bags per morgen is well below that of between 7.5 and 10.75 bags obtained by the more efficient growers. Use of hybrid maize would be of some help, but bettering of other conditions, e.g., improvement of soil structure and fertility, adequate control of weeds, pests, diseases and water evaporation are, on the basis of reports from Agricultural Research Stations, thought likely to be much more profitable. The close approach of demand to production makes the creation of reserve stocks,

and provision for their storage, matters of some importance.—D. Harvey.

BAUM, E. L., MEY, C. W., SHAW, A. O. and WALKUP, H. G. **Management practices and net returns in milk production in Washington.** *J. Dairy Sci.*, 1954, **37**, 14-21. [Dept. Agric. Econ., State Coll. Washington, Pullman.]

A sample of 244 individual 305-day lactation records out of a total of 28,968 was analysed according to week and month of calving. All cows had a grazing season of about 6 months. Having regard to milk prices in Western Washington during 1949-50 the most profitable months for calving were August and September and, in general, the least profitable March and April. Irrespective of date of calving the cost per cow or per gal. of milk was highest where it was the practice to use much grain with a fair amount of hay. Total costs for cows calving in the same month were influenced more by the amount of grain than by the amount of roughage given. It is concluded that the level of production per cow changes only the extent of the net returns and not the relation between the least and the most profitable month of calving.—W. Thomson.

5559

SHEPHERD, G., PURCELL, J. C. and MANDERSCHIED, L. V. **Economic analysis of trends in beef cattle and hog prices.** *Iowa Agric. Exp. Stat. Res. Bull.* No. 405, January 1954, pp. 726-743.

Since 1910 the ratio of cattle to pig prices at Chicago has increased at the rate of 1.2 per cent. yearly. The reasons given for these changes are: (1) there has been an increase in the percentage of urban consumers, who consume more than twice as much beef per head as country consumers, (2) occupations are less strenuous, so that there has been a decrease in consumption of carbohydrate foods and an increase in meat, (3) income has risen and become more evenly distributed and (4) competition between vegetable fats and lard has increased. It is estimated that these trends will continue at about the same rate, though over the next few years there may be a movement towards a closer price ratio as beef supplies increase from the larger herds built up while high prices rule. Beef prices will also continue to rise relative to disposable income as well as to pork prices, while, conversely, pork prices will continue to decline relative to income.—W. Thomson.

JAWETZ, M. B. **The combined effect of levels of stocking and yields per cow upon farm profits on dairy farms.** Dept. Agric. Econ., Univ. Coll. Wales, Aberystwyth, December 1953, pp. 27.

The records of 98 Welsh farms during 1951-52 were used to study the effect on profit of density of stocking with dairy cows, yield per cow and density of stocking with followers. The farms were considered as below or above average in each respect, giving 8 combinations. Allowance was made for subsidiary enterprises such as pigs and poultry in assessing the profit per acre.

Profit depended in the first place on a high rate of stocking with cows. High yields were next in importance, and these were complementary. Too heavy a rate of followers in relation to milking stock reduced profits. The possible effects of changes in the price of feedingstuffs and milk are discussed.—T. D. Bell.

STRUTT, C. W. **Australian beef. 1. Production and marketing.** *Agriculture, J. Minist. Agric. Engl.*, 1954, **61**, 73-76. [Office of the High Commissioner for the United Kingdom, Canberra.]

The difficulties of beef production in Australia are discussed. Climate excludes a large part of the country from any extensive production. The other major difficulty is transport: in many areas rail and mechanised road transport are not available, and droving is slow, costly and risky when water is not available.

Production has increased by 12 per cent. since 1939, and where the construction of road or railway is impracticable air transport may be possible and has already been tried on a small scale. An investigation of the economics of air transport and its extension are discussed.

5565

GRANT, A. **Hill farming in the North of Scotland.** *North of Scotland Coll. Agric., Agric. Econ. Dept. Econ. Rep. No. 38*, February 1954, pp. 21.

The 37 farms studied all had more than 50 per cent. of their land classified as rough grazing and permanent pasture. Twenty were termed upland rearing farms, with acreage ranging from 250 to over 1250. All except one carried a ewe flock and most had some breeding cows, though their relative importance varied considerably; pigs and poultry varied in importance. The number of lambs surviving per 100 ewes at opening valuation was 110, range 85 to 140, for farms under 1000 acres and 95, range 70 to 121, for those over 1000 acres. For these 2 sizes of farms the average net surplus per £100 rent, excluding management charge, was respectively £268 and £392 in 1952-53 compared with a loss of £157 and a surplus of £249 in 1951-52. The 1952-53 surplus was equal to 6½ per cent. interest on capital for the smaller and 9 per cent. for the larger farms. It is pointed out that, but for subsidies, the smaller farms in par-

ticular would have again showed a net loss. The other 17 farms were classified as hill sheep farms, with an acreage ranging from 888 to 14,162, of which 99 per cent. was termed rough grazings. Ewe flocks varied from under 250 to 1374 and 9 farms carried from 4 to 27 cows. The average number of lambs sold or retained per 100 ewes at weaning was 77, range 54 to 105. The net surplus was £87 per 100 ewes or 11½ per cent. interest on capital. On farms where sheep were the only stock there was no direct subsidy.—W. Thomson.

5566

BREIERM, K. Husdyrbrukets plass i norsk landbruk. [**The place of animal husbandry in Norwegian agriculture.**] *Landbrukshøgsk. Inst. Husdyrernæring Foringslære*, Repr. No. 128, 1953, pp. 11.

Three-quarters of farm land in Norway is under grass. Agricultural policy is discussed in relation to that fact and to the recommendations of FAO and experiences elsewhere. Of the gross earnings of agriculture in Norway in 1951-52, 78.7 per cent. came from animal husbandry and 41.6 per cent. from milk. It is argued that it is sound policy to continue to regard milk as the most important and most economical product, to improve milk production by improving stock and to increase as far as possible the use of home-produced feeding-stuffs.—I. Leitch.

DIET IN ETIOLOGY OF DISEASE

GENERAL

5567

SCARISBRICK, R. **Acid indigestion in a sheep fed on mangolds.** *Vet. Rec.*, 1954, **66**, 131-132. [Dept. Animal Pathol., Univ. Cambridge.]

A Suffolk wether of bodyweight about 150 lb., fitted with a rumen cannula, was offered 16 lb. instead of its usual 12 lb. of mangolds daily. It ate only 15 lb. and next morning was found to be distressed and acutely lame in all 4 feet, which were hot to the touch. It recovered spontaneously within a few days.

During this illness, there was at first the normal increase in rumen volatile fatty acids and ammonia, but then the ammonia level continued to rise unusually high and the fatty acid level fell away before attaining its usual normal value; it subsequently became very low. Lactic acid concentration was very high indeed. Rumen pH was 4.7. During recovery the picture gradually returned to normal.

It was considered that the normal mechanisms for absorption and neutralisation of acid must have been put out of action, but it was not possible

to reproduce the syndrome in other sheep by feeding them on mangolds. However, signs of ruminal stagnation have followed the administration of dilute mineral acid when the rumen pH has fallen below 5. A similar condition followed the administration of 500 g. glucose.

It was concluded that the rapid production in the rumen of an amount of acid of the order of 1 g. equiv. may overwhelm the neutralising capacity immediately available, and that the resulting acidity interferes with those neutralising mechanisms that act more slowly. The slower production of considerably more acid can be tolerated without difficulty.—W. A. Greig.

5568

LINDAHL, I. L., COOK, A. C., DAVIS, R. E. and MACLAY, W. D. **Preliminary investigations on the role of alfalfa saponin in ruminant bloat.** *Science*, 1954, **119**, 157-158. [Animal and Poultry Husb. Res., Agric. Res. Centre, Beltsville, Md.]

Saponins were recovered from alfalfa by a method outlined.

Before the animal tests began, the experimental ruminants were subjected to preliminary tests for susceptibility to bloat by pasturing on alfalfa or ladino clover for several days and then drenching with ladino clover or alfalfa juice. Saponin was then administered, dissolved in 1 to 2 pints of water, by stomach tube.

In 5 sheep and 1 goat receiving 15 to 25 g. saponin, distension of the rumen was light moderate to moderate; in 1 sheep receiving 55 g. it was moderate to severe; and in a heifer given 75 g. it was light moderate. In general, peak distension occurred after 30 to 45 min. compared with 10 to 15 min. after drenching with juice.

Several attempts to produce bloat in sheep on grass pasture by giving alfalfa or ladino juice all failed; but when one such sheep was given 15 g. saponin slight distension resulted. The same animal given 25 g. saponin after grazing a ladino pasture developed distinct distension. A mature goat given 15 g. saponin did not become distended, but was also relatively resistant to ladino juice. In all cases distension appeared to be due to gas rather than froth.

No detectable reaction was given by 2 commercial saponin solutions, nor by 25 g. of a household detergent.—W. A. Greig.

LINDLEY, C. E., TAYSOM, E. D., HAM, W. E. and SCHNEIDER, B. H. **Urinary calculi in sheep.** *J. Animal Sci.*, 1953, 12, 704-714. [Washington Agric. Exp. Stat.]

Nine groups of 6 ram lambs were used to find the effects of high intake of CaCO_3 , MgCO_3 and K_2HPO_4 on the formation of urinary calculi. The data indicate that P was the cause of the highest incidence of calculi. Deficiency of carotene or vitamin A in the diet was not involved. Water intake and rate of urine excretion were higher in groups with higher incidence of calculi. Data on blood and urine analysis are presented.—J. C. Gill.

5572

LEOSCHKE, W. L. and ELVEHJEM, C. A. **Prevention of urinary calculi formation in mink by**

alteration of urinary pH. *Proc. Soc. Exp. Biol. Med.*, 1954, 85, 42-44. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Chemical analyses of mink calculi had shown that the main component was $\text{MgNH}_4\text{PO}_4 \cdot 6\text{H}_2\text{O}$. Tests *in vitro* showed that although this salt is soluble in water at pH 6 or less, solubility drops rapidly between pH 6 and 7.5.

The addition to the normal ranch diet of 1 g. NH_4Cl per mink daily reduced urine pH from an average of 6.4 (range 5.5 to 7.5) to 5.7 (range 5.5 to 5.9).

A group of pregnant mink were then given this supplement from 22 April to 22 May, i.e., the period when urinary calculi most frequently form in this class of animal. Only 1 of 200 mink fed in this way died from urinary calculi; 16 of 400 control animals were lost from this cause. In a later field trial on commercial ranches, NH_4Cl was given from 10 April to 1 June. A total of 40,000 mink each received 0.5 g. NH_4Cl daily, and losses varied from 0.5 to 3 per cent.; but in 10,000 mink receiving double this quantity losses were less than 0.2 per cent.

It was concluded that 1 g., but not 0.5 g., NH_4Cl per animal daily will prevent urinary calculi in breeding female mink.—W. A. Greig.

WITZKE, O. **Indikationsgebiete für Aminosäurenpräparate in der Veterinärmedizin unter besonderer Berücksichtigung von Tetrhomin und Keratyp.** [Indications for the use of amino-acid preparations in veterinary medicine, with special reference to Tetrhomin and Keratyp.] *Berl. Münch. tierärztl. Wochenschr.*, 1954, 67, 93-95. [Berlin.]

Keratyp is a preparation suitable for injection containing 9 per cent. of total amino-acids, of which 1.5 per cent. is cystine-cysteine, 1.5 per cent. methionine, 0.5 per cent. glutamic acid and 0.3 per cent. tyrosine, the remaining 5.2 per cent. being a mixture of 9 other amino-acids. Tetrhomin is a combination of the above with thiocyanic acid. This latter preparation is recommended for use in infectious disease, including puerperal fever. Keratyp is recommended for acetonuria and acute liver disease, puerperal haemoglobinuria, hypocalcaemia and tetany, along with calcium treatment in the 2 latter. It is of use also after operations.—W. Godden.

DEFICIENCY DISEASES

5575

PAVLOV, A. A. Klinitzeskie proyavleniya mineral'nogo golodaniya u sel'skokhozyaistvennykh travoyadnykh zhivotnykh. [**Clinical manifestation of mineral deficiency in herbivorous farm animals.**] *Veterinariya*, 1953, **30**, No. 7, 39-40.

The importance of dietary salts in correct proportions is emphasised by observations of deficiency in cattle and horses in a number of localities, particularly in Kazakhstan and Kirgizia, although the content of salts in the soil in these regions is very high. The disorders, including rickets, osteomalacia and pathological fractures, are obviated by adding bonemeal or commercial phosphate preparations to the diet. Deficiency is commoner towards the end of the period spent in stall, and is thought to be due to deficiency of vitamins concerned in the assimilation of Ca and P.

D. W. Taylor.

5576

KRÜGER, W. Ist die Rinderleukose eine Mineralstoffmangelkrankheit? [**Is leucosis in cattle a mineral deficiency disease?**] *Berl. Münch. tierärztl. Wochenschr.*, 1954, **67**, 149-153. [Inst. Milhyg., Bundes-Versuchsanst. Milchwirtsch., Kiel.] English summary.

The possibility that mineral deficiency may have something to do with leucosis in cattle is discussed. In Germany the disease is confined to the North German plain, which was subject to glaciation, so that many of the soils are poor in minerals. Recent results by Wehrmann (*Dissertation*, Kiel, 1953) on the manganese, copper and cobalt contents of Schleswig-Holstein pastures are quoted; pastures on podsols and low moor are liable to be deficient in Cu and Co. But leucosis occurs on other soils and, on the other hand, is relatively uncommon in a "Lecksucht" (pica) region just south of the Danish border.

An outbreak in a dairy herd on an experimental farm of the *Institut für Milchhygiene* coincided with a period when the pasture had not been receiving its usual treatment with fertilisers containing Cu and Co and owing to the war the protein: starch ratio of the indoor ration had been narrowed by the use of distiller's spent wash from milo (sorghum) offal, with rapeseed cake and home-grown hay. The disease attacked cows only, not calves, and only those with yields above average. With a return to normal conditions the number of cases gradually decreased. Nevertheless in 1950

an experiment, which still continues, was begun in which half the cows were given 2 or 3 table-spoonfuls daily during the stall-feeding period of a mineral supplement (supplied by the firm Bayer, Leverkusen) containing Ca, P, Mg and the trace elements Cu, Mn, Zn, Co, Fe, I and B. The others were given a commercial mineral mixture. Of the 3 cows and 2 heifers subsequently found to have leucosis, none had had the Bayer mixture. The numbers are too small for firm conclusions to be drawn and further investigation will be necessary to find out which, if any, of the constituents of the Bayer mixture is effective.—W. M. Deans.

5578

NIKONOV. Solevoe golodanie telyat. [**Salt deficiency in calves.**] *Veterinariya*, 1953, **30**, No. 5, 45.

The pasturing of a dairy herd on certain meadows in autumn, and feeding in winter on hay from the same meadows, was followed by the appearance of peculiar signs in the newborn calves. The hay had little chloride and no sodium. Salt was not added to the ration. The animals exhibited apathy, painful diarrhoea and pinkish spots round the nostrils, and refused to take milk. Death ensued in 3 to 5 days. Principal findings at post mortem were punctate haemorrhages in the gastric and intestinal mucosa and sometimes in the endocardium and under the renal capsules. The bacterial flora was normal. The condition responded only, but completely, to the administration of 1 per cent. NaCl solution.—D. W. Taylor.

5579

GRATER, G. S., OSBORNE, A. D. and WHITE, J. B. **Sudden death of cattle attributed to peracute hypomagnesaemia.** *Vet. Rec.*, 1954, **66**, 161-162. [Salisbury.]

An Ayrshire herd was transferred on 24 June from a farm on heavy clay soil to one on light chalk soil and turned on to a permanent pasture containing a moderate admixture of clover. Within 10 days 3 cows, all of which had calved less than 2 months earlier, died suddenly without showing signs of illness. At post-mortem examination all were found to have enlarged spleens which had ruptured with extensive haemorrhage. One animal also had acute congestion of the abomasum, and another exhibited haemorrhages into the muscular portion of the diaphragm, the peritoneal and mucous surfaces of the abdominal alimentary viscera, and the endocardium; its chest cavity contained between 1 and 2 gal. blood.

Extensive investigations revealed no evidence of infection or poisoning. Two of 6 surviving cows examined had serum Mg levels below 2 mg. per cent.; they had been maintained under the same conditions but were at a more advanced stage of lactation. On this evidence, peracute deficiency of magnesium was diagnosed.

Unusual features of the outbreak included the extremely rapid onset and course of the condition, the absence of any history of typical cases on the farm, and the consistent finding of rupture of the spleen.—W. A. Greig.

BALLOT, H. Un trouble du métabolisme de nature carentielle. Dégénérescence graisseuse du foie chez l'agneau. [Metabolic disturbance of the nature of a deficiency. Fatty degeneration of the liver in lambs.] *Bull. Acad. vét. France*, 1953, **26**, 583-587.

In a flock of sheep of the Île de France breed, 30 lambs died of a wasting disease at the age of 6 months. At post mortem the livers were greatly enlarged, pale in colour and infiltrated with fat. The protein content of the diet had been reduced when the wasting disease first appeared. As treatment the protein content was increased again, and each lamb was given 2 injections of 75 mg. methionine 4 days apart. Two very sick lambs died, but the others recovered rapidly.

BODA, J. M. and COLE, H. H. The influence of dietary calcium and phosphorus on the incidence of milk fever in dairy cattle. *J. Dairy Sci.*, 1954, **37**, 360-372. [Div. Animal Husb., Univ. California, Davis.]

Purebred Jersey cows which had calved at least 3 times were selected from a herd with a high incidence of milk fever and were divided into 4 groups. Group 1, 14 cows, received alfalfa hay to appetite during the whole dry period of 2 to 3 months; the Ca:P ratio of the hay was 6:1. Group 2, 16 cows, received for from 9 to 73 days before calving a low-Ca, high-P diet of oat hay and ground barley, with monosodium phosphate; the Ca:P ratio was 1:3.3. Group 3, 20 cows, received for from 5 to 45 days a diet also composed of oat hay and ground barley, with spent bone black; Ca:P ratio 1:1. Group 4, 19 cows, received the same ration as group 3, but with CaCO₃ instead of bone black; the Ca:P ratio was 5.9:1, but the Ca and P intakes were higher than on alfalfa hay. After calving, blood samples were

taken and all the cows received the usual ration of the herd.

In the 4 groups the incidence of milk fever was 5, none, 3 and 5, respectively. Four of 8 cows which did not develop milk fever on the low-Ca, high-P diet developed milk fever in the next lactation when they received a high-Ca diet before calving.

It is suggested that a low Ca, high P diet before parturition is an effective preventive of milk fever, and that this is due to stimulation of parathyroid activity as a response to the low Ca intake.

POISONS OCCURRING IN FOOD

5583

PICKUP, J., WORDEN, A. N., BUNYAN, J. and WOOD, E. C. Chronic constipation in dairy cattle associated with a high level of zinc in the water supply. *Vet. Rec.*, 1954, **66**, 93-94.

Chronic constipation developed in a pedigree Jersey herd in early winter, and, despite treatment, persisted until April when stall-feeding ceased. All classes of animals were affected, including the stock bull and young calves. In lactating animals, milk yield fell.

The same trouble recurred the following winter in a milder form, and its cause was traced to the water supply, which proved to contain up to 8 p.p.m. Zn. Presumably Zn had been released from the galvanised coating of the storage tanks as a result of electrolytic reaction with the copper pipes supplying the cowshed. Deposits found in the water bowls were shown to consist of CaCO₃ with traces of Mg and Zn, from which it was concluded that the water supply had contained appreciable quantities of Zn for some time past.

The storage tanks were cleaned and treated with bitumastic paint, after which no further trouble was experienced.—W. A. Greig.

COPENHAVER, J. S. and BELL, W. B. The production of bovine hyperkeratosis (X disease) with an experimentally made pellet feed. *Vet.*

N.A. and R., October 1954

Med., 1954, **49**, 96-101; 106. [Dept. Animal Husb., Virginia Agric. Exp. Stat., Blacksburg.]

Pelleted feed was prepared in 4 lots of one ton each in a pellet mill. For the preparation of lots A and B the lubricant for the rolls of the mill contained no highly chlorinated naphthalene, while that for lots C and D did. For lots A and C the rolls were lubricated only once, before the pelleting process began; for lots B and D the lubricant was introduced in small quantities at 10-min. intervals.

The 4 lots of pellets were subsequently given each to 2 calves, feeding the pellets within each lot given in the order in which they were made. Calves on lots A and B all remained in every way normal, but those on lots C and D had poor appetites, made poor weight gains and had low blood vitamin A levels; all developed typical signs of bovine hyperkeratosis and at autopsy displayed typical lesions, of which full details are given. The calves on lot C were most affected, one dying after 41 days and the other being killed when moribund after 82 days.

Two calves were given the lubricant containing chlorinated naphthalenes by mouth and developed hyperkeratosis; 2 calves given the other lubricant remained healthy.

Two further calves were given lot C pellets, one from the place where the first 2 calves left off (only about 9 per cent. of the lot had been consumed) and the other starting with the last bag and moving backwards. The first calf developed severe hyperkeratosis but the second became only very mildly ill, indicating that the toxic substance in the lubricant had been concentrated in the first portion of the lot.—W. A. Greig.

PRIBIĆEVIĆ, S. and ŠEVKOVIĆ, N. [A contribution to the experimental study of cockle-bur (*Xanthium saccharatum*) poisoning.] *Acta vet., Belgrade*, 1954, **4**, 58-64. [Inst. Animal Nutrit.] English summary.

Cockle-bur given to pigs at the rate of 1.5 per cent. of liveweight or more killed them in 10 to 15 hr. When the plant was introduced gradually at lower levels tolerance developed and that amount could be exceeded without ill effect. An aqueous extract at 1.1 to 1.3 per cent. of liveweight, given subcutaneously, was fatal to rats and mice. The active principle was thought to be a glucoside. Post-mortem appearances showed gastro-enteritis, liver, spleen and kidney degeneration, and haemorrhage. (From summary.)—J. S. Thomson.

SPEDDING, C. R. W. Pasture management to control worms in sheep. *Agriculture, J. Minist. Agric. Engl.*, 1954, **61**, 51-54. [Grassland Res. Stat., Stratford on Avon.]

Helminth infestation was prevented in lambs by strip grazing on new pasture. The lambs were moved to a fresh strip every 2 days and did not return to the old strips. It was 11 months since any animal had been on the ground, when it was grazed as stubble. The ley was sown as a direct seeding following an oat crop. This treatment appeared to be sufficient to produce a clean pasture. Further observations on ewes and their lambs suggest that strip grazing on clean pasture reduces helminth infestation to negligible amounts.

7. BOOK REVIEWS

5594

PLANT, M. **The domestic life of Scotland in the eighteenth century.** University Press, Edinburgh, 1952, pp. xi + 319.

This interesting picture of family life in Scotland in the eighteenth century is painted largely from information obtained from the household accounts of Lady Grisell Baillie, Sir John Foulis and others of the nobility and from the written impressions of travellers from England and the Continent. It is not surprising, therefore, that one sees fairly clearly how the laird lived but not so clearly how his tenants lived. Despite this disadvantage, the book should find favour as an informative, well documented, and sometimes amusing account of the times.

The chapters entitled "The kitchen and the cook" and "Food and drink" suggest that the Scottish laird entertained his guests in much the same lavish fashion as did his English counterpart, although it is suggested that more simple food sufficed when the visitors had gone. Plain fare in Scotland was based largely on oatmeal, which appeared as pottage, brose, bannocks, kale, or sowans, according to the time of day. Salt beef, cabbage, fish in many districts, milk, and potatoes in the second half of the century, supplemented the oatmeal dishes. Bread was little used and Adam Smith is reported to have attributed the poor health of Scots compared with English to the Scottish diet of oatmeal. The chapter in this book on "Health and sanitation" indicates that the causes of Scotland's higher rates of sickness and mortality were more probably overcrowding and poor sanitation than diet.—F. C. Aitken.

5595

BOGERT, L. J. **Nutrition and physical fitness.** W. B. Saunders Company, Philadelphia, 1954, 6th ed., pp. xiv + 664. Price 22s. 6d.

The study of nutrition is a scientific discipline, but nutrition is not a scientific entity: it is a meeting place of such sciences as chemistry, physics and biology.

This edition of a well-established text has been largely re-written, so that it is rather surprising to find that the author still adheres to his original purpose to make nutrition "understandable to

those without previous knowledge of Chemistry" And there is no reference to a need for a previous knowledge of biology: all the book supplies is a meagre section on "Body Processes" well on in the text and occupying less than 100 out of 600 odd pages.

This is not indeed a bad book: it deals at considerable length with the nature of foodstuffs, says a little about alimentation, metabolism, excretion and endocrinology, and then goes on to the planning of meals and the principles of dietetics. Each chapter, too, has a useful bibliography. Moreover, quite copious references are given at the foot of many of the pages. In short, this book is quite a considerable text in nutrition but certainly not fully comprehensible to those without some knowledge of chemistry and of biology. There is no short cut to a proper understanding of nutrition.

5596

DØSSING, J. **Determination of individual normal weights of school children.** Publ. No. 28 from Univ. Inst. Human Genetics, Copenhagen 1952, pp. 105. Ejnar Munksgaard, Copenhagen.

This thesis starts with a historical review of publications dealing with weights and heights of children, and goes on to detail the different methods proposed for judging the normality or otherwise of individual weight measurements, including various indices, charts, regressions on other body measurements, and tables. These methods all have the same defect, that they depend on average values and measures of dispersion found from measurements of numbers of children, while each child is believed to have his own individual normal weight, and it is the deviation from this value that is important, rather than that from an average value.

An analysis is described of weight and height data for 8786 boys and 8673 girls from elementary and secondary schools in Copenhagen, excluding children with chronically inhibited growth. For each child at least 6 pairs of measurements were available from routine annual examinations, with heights in the range 120 to 180 cm. and age range about 7 to about 18 years. Over this range it is found that average weight is related to average height by a relation of the form $w = ch^m$, so that

N.A. and R., October 1954

if average results are plotted on double logarithmic scales a linear relationship is shown. Measurements for individuals may also be plotted in this way and the best straight line through the points may be taken to define the characteristic weight of the child for each height attained. The mean variabilities of the measurements from these individual lines, measured by standard deviations, have been calculated for boys and for girls. They are found to be independent of height, and to be considerably smaller than the variabilities about average weight. The distribution of the slopes, and of the levels of the lines for a fixed height, is found to be approximately normal, indicating that there is a continuous transition from a slender to a stocky type of body build.

Charts have been designed to facilitate the assessment of weight measurements and growth. A separate chart is kept for each child, weight being plotted against height on double logarithmic paper. After several measurements have been made it is possible to estimate the level and slope of the growth line. Long-term conclusions may be drawn from the relation of the level and slope to average values, short-term conclusions from the deviations of further individual points from the line in terms of the standard deviation.

A number of examples are given of the use of the charts, with details of the case history of the child in each case.

In conclusion, a statistical section gives methods of calculation and details of the construction of the charts.—I. McDonald.

5597

COSTA, D. *Calcio, leite e alimentação humana. [Calcium, milk and human diet.]* SAPS, Rio de Janeiro, 1953, pp. 102. English summary.

This attractively covered and well printed book, which is little more than a pamphlet, has been prepared, presumably for use in popular education, for SAPS, Serviço de alimentação da Previdência Social. Professor Costa commences on the grand scale with a general review of human nutrition, and especially of its sociological implications, and ends with a description of a single experiment on the availability of calcium in milk for rats.

Chapter 1 is a "Panorama of the problems of human nutrition". It surveys the role of diet in the growth, health and character of individuals and races and touches on the much discussed question of the growing world population. The development of the science of nutrition is important but the part played by instinct in the choice of food should not be neglected. The science which denied the importance of instinct "would be a dead science, turned against life itself."

In chapters 2 and 3 we come from the general

Vol. 24, No. 4

to the particular, with a review of the roles played by calcium in the body and an estimate of requirements. Requirements of Brazilians are considered to be less at all ages than those suggested in the literature for the United States and Britain.

Chapter 4 returns to world food problems with reference to regional differences in the composition of foods and of the diet as a whole. The dependence of man on the soil on which he lives is brought into discussion before the narrower theme of sources of calcium in the Brazilian diet.

Conditions which affect the utilisation of calcium are discussed in chapter 5. Foods must be judged not only on the quantity of calcium they contain, but also on its availability, which may depend upon many other constituents of the diet, such as fats, oxalates, roughage and substances which affect the pH of the intestinal tract. A few plants, such as lettuce and watercress, are rated as sources of calcium as highly as milk in respect of availability. The quantities supplied would, of course, be relatively minute.

The last chapter is devoted to an experiment which showed that 87 per cent. of the calcium in dried skimmed milk was utilised by growing rats. Half a litre of milk daily is enough to cover 58 per cent. of the calcium requirement of the Brazilian adult, assuming that utilisation is comparable in adult men and in growing rats, a dangerous assumption, surely.

The book is clearly printed and has a brief summary in English. There are errors in Table 4, on the calcium requirements of children aged 4 to 6 and 7 to 9 years.—D. Duncan.

5598

PATWARDHAN, V. N. and RANGANATHAN, S. *The nutritive value of Indian foods and the planning of satisfactory diets.* *Health Bull.* No. 23, 4th ed., 1951, pp. ii + 79. [Nutrit. Res. Labs., Indian Res. Fund Assoc., Coonoor.]

Health Bulletin No. 23 appeared first in 1937 bearing the name of the then Director of the Nutrition Research Laboratories at Coonoor, Dr. Aykroyd. Now in its fourth and fully revised edition by the present Director and Chief Chemist, Drs. Patwardhan and Ranganathan, it has continued successfully to fulfil two demands, the one for an elementary textbook on nutrition for Indians and the other for a compilation of data on the composition of foods suitable for use by those particularly responsible for the feeding of groups of the population in the Indian sub-continent and the Far Eastern archipelagos. The value of these tabulated data has been enhanced by the inclusion of new tables which give the common English name, the botanical name and their equivalents in 9 of the more important languages spoken in these parts.—D. Harvey.

5599

JOHNSTON, J. A. **Nutritional studies in adolescent girls and their relation to tuberculosis.** Charles C. Thomas, Springfield, Illinois, 1953, pp. xi + 320. Price 55s.

The main purpose of this study was an attempt to correlate nutritional state, as measured by retention of N and Ca, with the course of tuberculosis in adolescent girls. About two-thirds of the book is devoted to case reports of long-term Ca and N balance studies in 26 girls. Data are given also of B.M.R. measured at intervals of 6 days throughout the studies. Clinical notes and X-ray photographs indicate the course of the disease.

The study was begun during a 20-year X-ray study of 932 child reactors to tuberculin removed from their sources of infection, when it was found that of 29 who showed endogenous re-infection 21 were girls and of these 12 developed the infection within the period covered by the 2 years preceding and 3 years succeeding the first menstrual period. The 26 subjects of the nutritional study included 9 of those listed as cases of re-infection.

As a background to the main study data are tabulated of Ca and N balances and B.M.R. in a group of 8 healthy control girls and observations on other 3 are reported in detail. Small groups or single subjects were used in studies of the effects of thyroid, sex hormone, adrenal hormone, or chronic focal infection, such as infected tonsils, on Ca and N metabolism and for studies of the amounts of Ca and vitamin D required in adolescence and the effect of cevitamic acid on Ca metabolism. The effect of exercise on Ca and N metabolism was studied in a small group of children with tuberculosis.

In the main study there appeared to be a positive correlation between adequate storage of N and a favourable course of the infection. Storage of Ca seemed to be of importance in the preservation of the integrity of the primary lesion but not in the healing of the re-infection. A diet providing an energy intake of basal plus 70 per cent. with 15 per cent. of calories from protein was adequate for good storage of N in most subjects. In some, amino-acids or powdered milk were useful to increase N intake. Supplements of dicalcium phosphate and/or vitamin D were given to some with inadequate Ca storage.

The background studies indicated that in adolescence there is a prepubertal period of accelerated growth, high B.M.R. and increased capacity for N and Ca retention, and a post-pubertal period of deceleration in rate of growth, low B.M.R. and diminished ability to retain N and Ca. Hypo- and hyperthyroid states were accompanied by diminished storage of N and Ca. Administration of thyroid in hypothyroidism increased retentions. Oestrogens diminished retention of N and Ca in

girls and testosterone increased N and decreased Ca retention in boys. Focal infection, e.g., infected tonsils, depressed N retention. In tuberculosis patients allowed moderate exercise N and Ca retention improved. The Ca requirement of the adolescent girl appeared to be 1.3 to 1.5 g. daily and 1000 I.U. vitamin D was considered to be necessary. The results of a study of the effect of cevitamic acid on Ca retention were inconstant.

The findings are discussed in relation to the management of tuberculosis in adolescents, and it is concluded that the most important contribution that can be made to the prevention of endogenous re-infection in the tuberculin reactor is the ensuring of normal retentions of N and Ca; this involves the provision of an adequate intake and a thorough consideration of all conditions influencing utilisation.—F. C. Aitken.

SELYE, H. and HORAVA, A. **Third annual report on stress.** Acta, Inc., Montreal, 1953, pp. 637. Price 80s. net.

The reviewer is not ashamed to admit, with Belloc, that :

"The argument is much too wide
And much too deep and much too hollow,
And learned men on either side
Use arguments we cannot follow."

Nevertheless, the bulk of this volume consists of classified references, bringing its predecessors up to date. It will be useful to those who can follow the development of Selye's concept of stress, and to those who are interested in recent work on the hormones elaborated by the adrenal cortex. The book begins with an introductory review and includes 3 special articles : by J. T. Wortham and J. W. Headstream on "The effects of bilateral total adrenalectomy in diabetics"; by R. W. Porter on "Neurophysiological aspects of the control of ACTH secretion"; and by D. M. Green on "Hypertension". Finally, there is a "Sketch for a unified theory of medicine" which demonstrates clearly that Selye's disciples must master a difficult terminology and philosophy before they attain grace. The reviewer comforted himself by reading R. C. Garry's review of Selye's original monograph (Abst. 6280, Vol. 20).—A. M. Thomson.

OGINSKY, E. L. and UMBREIT, W. W. **An introduction to bacterial physiology.** W. H. Freeman and Co., San Francisco, 1954, pp. xi + 404. Price 51s.

The authors of this book have successfully resisted two temptations which beset all writers and are a common cause of bad textbooks. The first error is the rigid exclusion of all uncertainty, so that the reader reaches the last page feeling that he has mastered a closed and finished science. The other now very popular fault is to employ such an excessive sprinkling of doubt and qualification that all that remains memorable of the dish is the seasoning. Avoiding these temptations, Oginsky and Umbreit have produced a work which will give

pleasure to teachers and the minimum of pain to students, for whom the book is intended.

In the reviewer's opinion there are only 4 modern, advanced, textbooks of bacterial physiology; and the best of these covers a limited range of topics. The most comprehensive of the 4 is so unselective that it can be used only as a reference book. But even if the field were crowded this new work would have no difficulty in finding a place. Within the short space of 400 pages the authors deal briefly, but fairly, with all the important aspects of bacterial physiology. They have kept firmly before them their definition of the subject: "... a study of bacteria as examples of living material, a study of a form of life", with the result that the book possesses an unusual degree of coherence.

After a brief introduction to the nature and scope of bacterial physiology there is a compact outline of bacterial anatomy, the study of the individual cell. This is followed by a section on populations, covering growth, nutrition, the effect of the physical and chemical environment, and the genetics of bacteria.

The next section is concerned with the metabolism of bacteria and, in the course of about 150 pages it deals more than adequately with what is probably the most difficult aspect of bacteriology to teach coherently; the body of known facts grows rapidly, but many of the facts have not yet been fitted into a readily understood pattern. The chapter on energy can be highly recommended to all bacteriologists whose knowledge of thermodynamics is buried in a remote undergraduate past. The authors' novel treatment of this difficult subject throws some light on what for many bacteriologists is an obscure and confusing branch of cell chemistry.

Examples of other topics which are dealt with in later sections are adaptation, mechanisms of survival, and virulence as a physiological problem. Where shortage of space prevents a full treatment, well-chosen references provide an adequate guide to further study.

A final word should be said about 3 features in which this book excels. First, the illustrations are extremely good, apparently because an artist has made the drawings. Second, the references have been carefully selected and are usually accompanied by the authors' comments on the topic covered and the method of treatment used. Though restricted in number they provide a comprehensive cover of most aspects of bacterial physiology. Third, a list of questions is provided at the end of each chapter. These are so framed that they both provide the jaded examiner with new ways of wording old questions and encourage the student to think about what he has been reading.

The impression may have been given that this book is of interest only to teachers and students of

bacteriology, the audience for whom it was intended. In fact, the experienced bacteriologist will find much to stimulate his thought in the authors' new presentation of well-known material.

BROWN, D. **Methods of surveying and measuring vegetation.** *Commonwealth Bureau of Pastures and Field Crops, Bull. No. 42, 1954, pp. xv + 223.* Published by Commonwealth Agricultural Bureaux, Farnham Royal, Bucks. Price 35s. post free.

This book compiled by Miss Brown of the Commonwealth Bureau of Pastures and Field Crops should be read by every agronomist. The subject matter, dealing as it does with methodology, should have a wide appeal for biologists generally. The monograph is well illustrated, many of the photographs being of really excellent quality. Techniques of grassland measurement are reviewed as they concern the world-wide variety of environmental conditions including the various range lands of the tropics and sub-tropics, but chiefly those in more temperate zones. The book contains details of the numerous methods that have been found useful for botanical analysis, for measuring yields and utilisation applicable, in the aggregate, to all sorts of grassland, from the most intensive to extensive use of land. Many of the chapters will appeal to progressive farmers and pastoralists; for example, chapter 16 which deals with pasture recording should be studied and the findings might well be acted upon by progressive men in Britain and other countries. The chapters (14 and 15) concerning the animal and its production at pasture are excellent, although in places the author tends to go into too much detail, almost to the point of being unnecessarily repetitive. The chapter on the theory of sampling, contributed by G. M. Jolly, offers a well-reasoned theme, but there is one statement in it upon which the reviewer must comment. Methods of sampling are discussed and here the author writes (page 16): "In a pasture where the vegetation is highly variable . . . it may be advisable to work with quite a small unit, otherwise an undesirable amount of material may require to be sampled to give the required degree of accuracy. An extreme case of this type would be the sampling of an area of grassland mainly occupied by two species which tended to occur in large areas of say half an acre occupied almost solely by one species. . . . A very considerable increase in accuracy would be achieved by halving the size of the sampling unit and doubling the number of units [quadrats] . . ." The pasture agronomist must quarrel with this approach because the biologist ought first to define the limits of his plant associations and then take his measurements within each.

Quite clearly in the instance quoted there are 2 well-defined associations and it is both biologically and, I suggest, statistically unsound to examine them other than as 2 separate pasture units. The reviewer never tires of asserting to his fellow agronomists that they must tread warily of statistics—like fire or water, statistical treatment is an excellent, even indispensable, servant but an awfully bad master.

This monograph by Miss Brown is the outcome of long sustained study of the literature, and she is to be congratulated on a task well done. It is by no means easy to keep pace with the very rapidly expanding literature in the field of grassland and animal agronomy. Possibly for that very reason the book does not give adequate cover to works reported upon since 1949. One other aspect not dealt with at all (or given but the briefest mention) is that of grassland surveys. Such surveys as have been carried out in various parts of the world including Britain, New Zealand, Australia, N. Rhodesia, Kenya and Holland have provided valuable basic data, but the techniques of mapping and the field procedures differ widely from place to place. It is to be hoped that Miss Brown will add a chapter dealing with this subject when comes the time (as surely it soon must) to produce a second edition.

W. Davies (Herbage Abstracts).

DOEHNER, H. (Ed.) *Handbuch der Schafzucht und Schafhaltung. Band 4. Die Leistungen des Schafes. [Handbook of sheep breeding and sheep rearing. Volume 4. Sheep products.]* Paul Parey, Berlin and Hamburg, 1954, pp. xiv + 670. Price DM. 25.

The earlier volumes of the "handbook" deal with breeding, management, feeding and disease. Unfortunately they are out of print. Nearly two-thirds of this volume is devoted to wool, its morphology, chemistry and chemical structure, growth and strength, shearing, handling and processing from sorting to the dressing of the finished web. The section on meat production covers the choice and management of mutton sheep, the handling and processing of the meat, the judgement of quality and fat stock shows and finally statistics of production and consumption. Ewe's milk takes more space, with a historical review of its uses, and a brief review of composition and the external influences that affect it, and the processing of milk; a sub-section deals with colostrum. There are relatively short sections on skin and leather and on the value and use of sheep manure. Processing of the skin as fur is not dealt with.

The book is well printed and well bound. It is very well illustrated with diagrams, photomicrographs and photographs. The tabular material

is a mine of information. The text, of course, varies somewhat in style from one author to another; on the whole it is crisp and clear. But what is most attractive, and it is not often a "handbook" can be called attractive at all, is the combination of the scientific and the practical. Wool markets, knitting machines and hand looms give added interest to morphology and statistics. The importance of science for production and processing is everywhere clear.

Treatment is naturally from the point of view chiefly of German customs and methods, and it is not, strictly speaking, complete; no one book on such a subject ever could be. But for a general survey it is outstanding. If the earlier volumes are as good it is the more to be regretted that they are out of print.—I. Leitch.

5612

BARNETT, A. J. G. **Silage fermentation.** Butterworths Scientific Publications, London, 1954, pp. x + 208. Price 27s. 6d. net. [Dept. Biol. Chem., Univ. Aberdeen.]

The first 4 chapters of this book are devoted to

the more practical aspects of silage making, including the use of acids and other additives, types of silo, and losses in the ensiling process. The chemical and biological processes are discussed in succeeding chapters and the remainder of the book is devoted to a somewhat unnecessarily detailed account of methods of analysis and a brief discussion of the nutritive value of silage. The grouping of some of the subjects which, as the author indicates in his introduction, may be open to criticism, appears to have led in some places to unnecessary repetition.

The book is well produced in clear type and is furnished with ample references to the literature. It seems a pity that the price of a book written primarily for the student should be so high.

Reprint of articles in *Monthly Bulletin of Agricultural Economics and Statistics*, 1954, 3, Nos. 5 and 6.

The State of Food and Agriculture 1954. Review and outlook. Rome, Italy, 1954. Pp. iv + 157. Price \$1.50.

The world review indicates that the upward trend of total agricultural production continued during the year ending in the middle of 1954. There was, however, a fall in trade as a result of good harvests. Farm prices fell in North America but were stable in Western Europe and in some areas, including the Far East, maintained a rising tendency. In general, agricultural development continued to be retarded by lack of investment funds.

Regional problems are considered in respect of the 8 main geographical areas. In Western Europe there is

Vol. 24, No. 4

need for stimulation of consumption by reduction of the costs of production, distribution and retailing. With the change in policy towards expansion of home consumption there seems little prospect of exports from Eastern Europe and U.S.S.R. becoming available. In North America production rose, exports remained much the same, and no decline occurred in domestic demand, with the result that stocks increased sharply. Exports from Latin America were higher in 1953 than in 1952, largely because of the recovery in Argentina. The acute phase of post-war shortage in the Far East has ended but, except in Japan, improvement in food consumption levels has been small. Demands for wool, meats and dairy products from Oceania have continued strong, but rising costs of production may provide difficulties. In the Near East there is need for a more intensified and diversified pattern of production. Of all regions Africa presents probably the most difficult problems with precarious economies to be diversified, internal markets to be developed, transport systems to be improved and dietary levels to be raised.

About one-third of the publication is taken up by the review of the present situation and outlook for 20 of the more important of the world's agricultural commodities.

FAO Nutrition Meetings Report Series No. 8. Report of the Third Conference on Nutrition Problems in Latin America. Caracas, Venezuela, 19-28 October 1953. Rome, Italy, June 1954, pp. 60. Price \$0.50.

This report differs from those on the earlier meetings at Montevideo in 1948 and at Rio de Janeiro in 1950 (see

p. 789, Vol. 20) in that repetition of numerous recommendations is largely avoided. One-third of it gives brief reference to 10 items: nutrition and food policy, extension of activities to rural areas, school feeding, nutrition of industrial workers, analysis of foods, dietary surveys, education in nutrition, place of nutrition in public health work, co-operation with workers in other professions, *e.g.*, education, and enrichment of food. The remaining two-thirds of the report deal with the more

detailed recommendations made by the Conference on the two subjects of protein malnutrition and endemic goitre.

The material prepared by the Venezuelan delegation has been referred to in Abst. 3571, Vol. 24.

Fisheries Study No. 3. Fish farming and inland fishery management in rural economy. Rome, Italy, July 1954. Pp. viii + 64. Price \$1.00.
